BAND Manual

Amsterdam Modeling Suite 2024.1

www.scm.com

Apr 05, 2024

CONTENTS

ONE

GENERAL

1.1 Introduction

The periodic DFT program **BAND** can be used for calculations on periodic systems, i.e. polymers, slabs and crystals. It uses Density Functional Theory (DFT) in the Kohn-Sham approach. BAND shares many of the core algorithms with ADF, although important differences remain (a noteworthy difference is that BAND uses numerical atomic orbitals as basis functions).

This User's Manual describes how to use the program, how input is structured, what files are produced, and so on. The *Examples section* (page 181) explains the most popular features in detail, by commenting on the input and output files in the $AMSHOME/examples/band directory.

Where references are made to the operating system (OS) and to the file system on your computer the terminology of UNIX type OSs is used.

The **installation** of BAND is explained in the Installation manual. There you can also find information about the license file, which you need to run the program.

Graphical User Interface (GUI) tutorials: GUI overview tutorials, BAND-GUI tutorials

This manual and other documentation is available at http://www.scm.com. As mentioned in the license agreement, it is mandatory, for publications in which BAND has been used, to cite the *lead references* (page 299).

1.2 Feature List

1.2.1 Model Hamiltonians

- *XC energy functionals and potentials* (page 13)

    - *LDA* (page 14), *GGA* (page 14), *meta-GGA* (page 16), *Model potentials* (page 18)

    - *Range-separated Hybrids* (page 21)

    - *GGA+U (Hubbard)* (page 23)

    - *LibXC library* (page 19)

    - *Grimme dispersion corrections* (page 16)

- *Relativistic effects: ZORA and spin-orbit coupling* (page 29) (including non-collinear magnetization)

- *COSMO* (page 30) solvation model

- Homogeneous *electric* (page 41) and *magnetic* (page 42) fields

1.2.2 Structure and Reactivity

- Geometry optimization, transition state search, linear transit, PES-scan, molecular dynamics via **AMS**. See the AMS Manual for details.

- Formation energy with respect to isolated atoms (which are computed with a fully numerical Herman-Skillman type subprogram)

1.2.3 Spectroscopy and Properties

- Normal modes, phonon dispersion curves (and related thermodynamic properties) and elastic tensor via **AMS** See the AMS Manual for details.

- Frequency-dependent dielectric function of systems periodic in one, two and three dimensions in the *Time-dependent Current-DFT* (page 95) (TD-CDFT) formalism

- *ESR and EPR* (page 104) (electron paramagnetic resonance) and *EFG* (page 106) (Nuclear Quadrupole Interaction)

- *Form factors* (page 109) (X-ray structures)

- *NMR shielding tensor* (page 106)

1.2.4 Charge transport

- *Non-Equilibrium Green's Function* (page 141) (NEGF) for calculating transmission function and current

- *Effective mass* (page 107) for electrons and holes mobility

1.2.5 Analysis

- *Various Atomic charges* (page 129), including Mulliken, Hirshfeld, CM5 and Voronoi

- Mulliken populations for basis functions, overlap populations between atoms or between basis functions

- *Densities-of-States* (page 121): DOS, PDOS and OPWDOS/COOP (see also: Band Structure and COOP tutorial)

- *Local Densities-of-States* (page 160) LDOS (STM images)

- *3D filed plotting of various properties* (page 134), such as orbitals (Bloch-waves), deformation densities, Coulomb potentials, …

- *Band Structure plot* (page 125) along edges of the Brillouin zone

- *Fermi surface* (page 128): (view with amsbands)

- *Fragment* (page 131) orbitals and a Mulliken type population analysis in terms of the fragment orbitals

- *Quantum Theory of Atoms In Molecules* (page 129) (QT-AIM, aka Bader Analysis). Atomic charges and critical points

- Electron Localization Function (*ELF* (page 157))

- Fragment based Periodic Energy Decomposition Analysis (*PEDA* (page 133))

- PEDA combined with Natural Orbitals for Chemical Valency (NOCV) to decompose the orbital relaxation (*PEDA-NOCV* (page 133))

1.3 What's new in Band 2024.1

- The unit of the DOS and PDOS is now states-per-unit-cell/energy. Before ams2024 this was multiplied by the energy interval, and had the unit states-per-unit-cell. To reproduce the old behavior use DOS%CompensateDeltaE=No.

- Restart of the DOS: i.e. calculate it from a previous calculation. This may be useful when you forgot to request it, or want to change the energy window/grid. In addition, a better k sampling can be used for the DOS only (compared to the k-grid used in the previous SCF calculation). See also the missing DOS problem addressed in *restarting the DOS* (page 162).
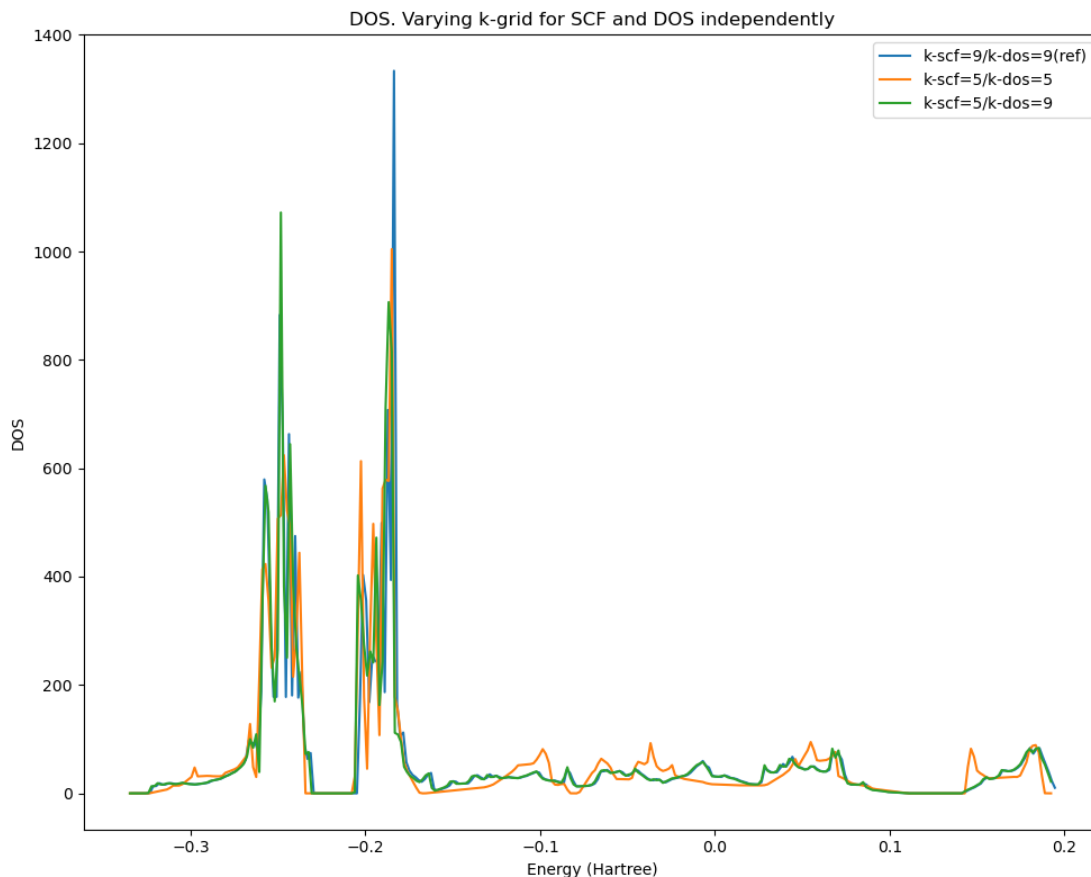

Fig. 1.1: DOS of a CuNiSlab. The best result is when using a 9x9 k-grid for both the SCF and the DOS calculation (blue curve). Using a worse 5x5 grid for both the SCF and the DOS produces a quite different DOS (amber). Doing the SCF with the coarser 5x5 grid and restarting the DOS with the finer 9x9 grid gives the green DOS, matching closely, and mostly hides, the best DOS (blue). See *Example: DOS and BandStructure from a previous calculation* (page 221).

- Restart of the BandStructure. This can be useful if you forgot to request it, or want to have it with a finer `BandStructure%DeltaK` key.

1.4 What's new in Band 2023.1

- Improved SCF convergence with the MultiStepper.
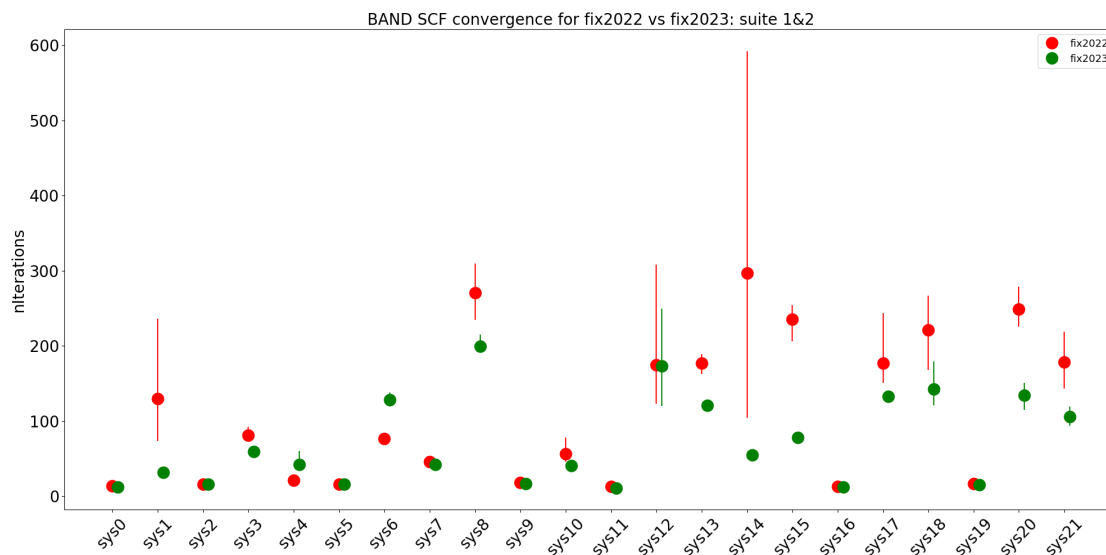

Fig. 1.2: Comparison of the number of SCF cycles needed. For easy systems there is not much difference, for more difficult systems, however, the fix2023 (green) is an improvement over the fix2022 (red). As there can be some randomness in the number of iterations (butterfly effect) the calculations are repeated five times (using a different number of cores), the dot is the average number of cycles used, and the vertical lines show the spread in the number of iterations (if any). The maximum number of iterations was set to 1000.

- Special (all electron) basis sets for comparison with literature data. Pure *STO* (page 51) basis sets for direct comparison with ADF, and pure *GTO* (page 51) basis sets as used by many other codes. Large GTO basis sets can also be useful for accurate MP2/RPA/GW calculations.
- MP2/RPA/GW for molecules
- TASKCC functional from Lebeda and coworkers (https://doi.org/10.1103/PhysRevResearch.4.023061). Compared to the TASKXC functional (good for band gaps) this improves atomization energies (the energy of open shell systems).

1.5 What's new in Band 2022.1

- Mulliken analysis (including PDOS) with spin-orbit coupling, see tutorial
- *Alternative elements* (page 57) (model impurities, fractional site occupancies)
- *Electron energy density function* (page 161), also known as X.
- *Fermi surface* (page 128), see tutorial

1.6 What's new in Band 2021.1

- The *D4(EEQ) dispersion correction* (page 17) can now be used for periodic systems.

- *r2SCAN-D4* (page 19) XC functional

- New AMS driver features can be used in combination with BAND. See the page What's new in the AMS driver for more details.

1.7 What's new in Band 2020

- New default: *Scalar relativistic ZORA* (page 29) is now enabled by default (in previous versions "non-relativistic" was the default).

- *Basis sets for Uue (Z=119) and Ubn (Z=120) added* (page 46)

- BAND can be used in QM/MM calculations with the new Hybrid Engine. See the Hybrid Engine manual and tutorial for more details.

- New AMS driver features can be used in combination with BAND. See the page What's new in the AMS2020 driver for more details (particularly important for BAND are the new strain-constraints and the periodic geometry optimizer improvements).

1.8 Input

The input options for Band are specified in a text file consisting of a series of key-value pairs, possibly nested in blocks. The input is usually embedded in an executable shell script. This is the content of a typical shell script for running a Band calculation:

```
#!/bin/sh

$AMSBIN/ams <<eor
   # This is the beginning of the input.
   # The input consists of key-value pairs and blocks.
   # Here we define the input option for the AMS driver:

   Task GeometryOptimization

   System
      Atoms
         H 0.0 0.0 0.0
         H 0.9 0.0 0.0
      End
   End

   # Next comes the Band "Engine" block. The input options for Band, which are
   # described in this manual, should be specified in this block:

   Engine Band
      Basis
         Type DZP
      End

      XC
```

```
        GGA PBE
    End
  EndEngine
eor
```

To run the calculation above from command-line you should:

1. Create a text file called, for example, `test.run` and copy-paste the content of the script above

2. Make the script executable by typing in your shell `chmod u+x test.run`

3. Execute the script and redirect the output to a file: `./test.run > out`

The program will create a directory called `ams.results`. Inside it, you will find the *logfile* `ams.log` (which can be used to monitor the progress of the calculation) and the binary results files `ams.rkf` and `band.rkf`. After the calculation is completed, you can examine the output file `out`. For more details, see the AMS documentation.

See also:

The *Examples* (page 181) section contains a large number of input examples.

Important: All options described in this manual should be specified in the Band Engine block:

```
# All Band keywords should be specified inside the 'Engine Band' block
Engine Band
   Basis
      Type DZP
   End

   XC
      GGA PBE
   End
EndEngine
```

1.8.1 General remarks on input structure and parsing

- Most keys are optionals. Defaults values will be used for keys that are not specified in the input

- Keys/blocks can either be *unique* (*i.e.* they can appear in the input only once) or *non-unique*. (i.e. they can appear multiple times in the input)

- The order in which keys or blocks are specified in the input does not matter. Possible exceptions to this rule are a) the content of non-standard blocks b) some non-unique keys/blocks)

- Comments in the input file start with one of the following characters: #, !, :::

```
# this is a comment
! this is also a comment
:: yet another comment
```

- Empty lines are ignored

- The input parsing is **case insensitive** (except for string values):

```
# this:
UseSymmetry false
# is equivalent to this:
USESYMMETRY FALSE
```

- Indentation does not matter and multiple spaces are treaded as a single space (except for string values):

```
# this:
    UseSymmetry     false
# is equivalent to this:
UseSymmetry false
```

- Environment variables in the input will be replaced by their value. We only support simple substitution of variables (optionally surrounded by {}). All other parameter expansion features of the POSIX shell (https://pubs.opengroup.org/onlinepubs/9699919799/utilities/V3_chap02.html#tag_18_06_02) (e.g. default values) are **not** supported. Expansion of a variable can be prevented by prefixing the leading dollar ($) with a backslash (\). Note that variables which are not set will expand to an empty string, just like in a shell:

```
File $SOME_DIRECTORY/file.txt
File ${SOME_DIRECTORY}_BACKUP/file.txt
Key  \$WILL_NOT_EXPAND
```

1.8.2 Keys

Key-value pairs have the following structure:

```
KeyName Value
```

Possible types of keys:

bool key The value is a single Boolean (logical) value. The value can be `True` (equivalently `Yes`) or `False` (equivalently `No`.). Not specifying any value is equivalent to specifying `True`. Example:

```
KeyName Yes
```

integer key The value is a single integer number. Example:

```
KeyName 3
```

float key The value is a single float number. For scientific notation, the E-notation is used (e.g. -2.5×10^{-3} can be expressed as $-2.5E-3$). The decimal separator should be a dot (`.`), and **not** a comma (`,`). Example:

```
KeyName -2.5E-3
```

Note that fractions (of integers) can also be used:

```
KeyName 1/3    (equivalent to: 0.33333333333...)
```

string key The value is a string, which can include white spaces. Only ASCII characters are allowed. Example:

```
KeyName Lorem ipsum dolor sit amet
```

multiple_choice key The value should be a single word among the list options for that key (the options are listed in the documentation of the key). Example:

```
KeyName SomeOption
```

integer_list key The value is list of integer numbers. Example:

```
KeyName 1 6 0 9 -10
```

Note that one can also specify ranges of integers by specifying the interval and (optionally) the step size separated by colons:

```
KeyName 1:5        (equivalent to: 1 2 3 4 5)
KeyName 2:10:2     (equivalent to: 2 4 6 8 10)
KeyName 20:10:-2   (equivalent to: 20 18 16 14 12 10)
```

Note also that ranges can be freely combined with individual numbers:

```
KeyName 1:5 10 20   (equivalent to: 1 2 3 4 5 10 20)
```

float_list key The value is list of float numbers. The convention for float numbers is the same as for Float keys. Example:

```
KeyName 0.1 1.0E-2 1.3
```

Float lists can also be specified as a range with equidistant points, by specifying the interval's boundaries (inclusive) as well as the number of desired subintervals separated by colons:

```
KeyName 1.0:1.5:5   (equivalent to: 1.0 1.1 1.2 1.3 1.4 1.5)
```

Range specifications can be freely combined with each other and single numbers:

```
KeyName 0.0 1.0:1.5:5 2.0:3.0:10
```

1.8.3 Blocks

Blocks give a hierarchical structure to the input, grouping together related keys (and possibly sub-blocks). In the input, blocks generally span multiple lines, and have the following structure:

```
BlockName
   KeyName1 value1
   KeyName2 value2
   ...
End
```

Headers

For some blocks it is possible (or necessary) to specify a *header* next to the block name:

```
BlockName someHeader
   KeyName1 value1
   KeyName2 value2
   ...
End
```

Compact notation

It is possible to specify multiple key-value pairs of a block on a single line using the following notation:

```
# This:
BlockName KeyName1=value1 KeyName2=value2

# is equivalent to this:
BlockName
   KeyName1 value1
   KeyName2 value2
End
```

Notes on compact notation:

- The compact notation cannot be used for blocks with headers.

- Spaces (blanks) between the key, the equal sign and the value are ignored. However, if a value itself needs to contain spaces (e.g. because it is a list, or a number followed by a unit), the entire value must be put in either single or double quotes:

```
# This is OK:
BlockName Key1=value Key2 = "5.6 [eV]" Key3='5 7 3 2'
# ... and equivalent to:
BlockName
   Key1  value
   Key2  5.6 [eV]
   Key3  5 7 3 2
End

# This is NOT OK:
BlockName Key1=value Key2 = 5.6 [eV] Key3=5 7 3 2
```

Non-standard Blocks

A special type of block is the *non-standard block*. These blocks are used for parts of the input that do not follow the usual key-value paradigm.

A notable example of a non-standard block is the `Atoms` block (in which the atomic coordinates and atom types are defined).

1.8.4 Including an external file

You can include an external ASCII file in the input with the `@include` directive:

```
@include FileName.in
@include "file name with spaces.in"
```

The file name should include the path, either absolute or relative to the run-directory. The content of the file is included in the input at the point where the `@include` directive occurs. The `@include` directive may occur any number of times in the input.

The `@include` feature makes it easy to pack your preferred settings in one file and use them in every run with minimum input-typing effort.

1.8.5 Units

Some keys have a default unit associated (not all keys have units). For such keys, the default unit is mentioned in the key documentation. One can specify a different unit within square brackets at the end of the line:

```
KeyName value [unit]
```

For example, assuming the key `EnergyThreshold` has as default unit `hartree`, then the following definitions are equivalent:

```
# Use defaults unit:
EnergyThreshold 1.0

# use eV as unit:
EnergyThreshold 27.211 [eV]

# use kcal/mol as unit:
EnergyThreshold 627.5 [kcal/mol]

# hartree is the atomic unit of energy:
EnergyThreshold 1.0 [hartree]
```

Available units:

- **Energy**: `hartree`, `joule`, `eV`, `kJ/mol`, `kcal/mol`, `cm1`, `MHz`
- **Forces**: `hartree/bohr`, `eV/bohr`, `hartree/angstrom`, `eV/angstrom`, `kcal/mol/angstrom`, `kJ/mol/angstrom`
- **Length**: `bohr`, `angstrom`, `meter`
- **Angles**: `radian`, `degree`
- **Mass**: `el`, `proton`, `atomic`, `kg`
- **Pressure**: `atm`, `pascal`, `GPa`, `a.u.`, `bar`, `kbar`
- **Electric field**: `V/angstrom`, `V/meter`, `a.u.`

AMS DRIVER'S TASKS AND PROPERTIES

BAND is an engine used by the AMS driver. While BAND's specific options and properties are described in this manual, the definition of the system, the selection of the task and certain (PES-related) properties are documented in the AMS driver's manual.

In this page you will find useful links to the relevant sections of the AMS driver's Manual.

2.1 Geometry, System definition

The definition of the system, i.e. the atom types and atomic coordinates (and optionally, the systems' net charge, the lattice vector, the input bond orders, external homogeneous electric field, external point charges, atomic masses for isotopes) are part of the AMS driver input. See the System definition section of the AMS manual.

2.2 Tasks: exploring the PES

The job of the AMS driver is to handle all changes in the simulated system's geometry, e.g. during a geometry optimization or molecular dynamics calculation, using energy and forces calculated by the engine.

These are the tasks available in the AMS driver:

- Single Point
- Geometry Optimization
- Transition State Search
- IRC (Intrinsic Reaction Coordinate)
- PESScan (Potential Energy Surface Scan, including linear transit)
- NEB (Nudged Elastic Band)
- Vibrational Analysis
- Molecular Dynamics

2.3 Properties in the AMS driver

The following properties can be requested to the BAND engine in the AMS driver's input:

- Atomic charges
- Dipole Moment (see also *Dipole moment and Berry Phase* (page 109))
- Dipole Gradients
- Elastic tensor
- Nuclear Gradients / Forces
- Hessian
- Infrared (IR) spectra / Normal Modes
- Thermodynamic properties
- PES point character
- Phonons
- Stress tensor
- Elastic tensor
- VCD (Vibrational Circular Dichroism)

MODEL HAMILTONIANS

3.1 Density Functional (XC)

The starting point for the XC functional is usually the result for the homogeneous electron gas, after which the so called non-local or generalized gradient approximation (GGA) can be added.

The density functional approximation is controlled by the XC key.

Three classes of XC functionals are supported: LDA, GGA, meta-GGA, and range-separated hybrid functionals. There is also the option to add an empirical dispersion correction. The only ingredient of the LDA energy density is the (local) density, the GGA depends additionally on the gradient of the density, and the meta-GGA has an extra dependency on the kinetic energy density. The range-separated hybrids are explained below in the section *Range-Separated Hybrids* (page 21).

In principle you may specify different functionals to be used for the *potential,* which determines the self-consistent charge density, and for the *energy* expression that is used to evaluate the (XC part of the) energy of the charge density. The *energy* functional is used for the nuclear gradients (geometry optimization), too. To be consistent, one should generally apply the same functional to evaluate the potential and energy respectively. Two reasons, however, may lead one to do otherwise:

1. The evaluation of the GGA part (especially for meta-GGAs) in the *potential* is rather time-consuming. The effect of the GGA term in the potential on the self-consistent charge density is often not very large. From the point of view of computational efficiency it may, therefore, be attractive to solve the SCF equations at the LDA level (i.e. not including GGA terms in the potential), and to apply the full expression, including GGA terms, to the energy evaluation *a posteriori*: post-SCF.

2. A particular XC functional may have only an implementation for the potential, but not for the energy (or vice versa). This is a rather special case, intended primarily for fundamental research of Density Functional Theory, rather than for run-of-the-mill production runs.

All subkeys of `XC` are optional and may occur twice in the data block: if one wants to specify different functionals for potential and energy evaluations respectively, see above.

```
XC
  {LDA  {Apply}   LDA {Stoll}}
  {GGA  {Apply}   GGA}
  {DiracGGA  GGA}
  {MetaGGA  {Apply}   GGA}
  {Dispersion {s6scaling} {RSCALE=r0scaling} {Grimme3} {BJDAMP} {PAR1=par1}
↪{PAR2=par2} {PAR3=par3} {PAR4=par4}}
  {Dispersion Grimme4 {s6=...} {s8=...} {a1=...} {a2=...}}
  {Model [LB94|TB-mBJ|KTB-mBJ|JTS-MTB-MBJ|GLLB-SC|BGLLB-VWN|BGLLB-LYP]}
  {SpinOrbitMagnetization [None|NonCollinear|CollinearX|CollinearY|CollinearZ]}
  {LibXC {Functional}}
```

(continues on next page)

```
    {DOUBLEHYBRID doublehybrid}
    {RPA {option}}
End
```

The common use is to specify either an LDA or a (meta)GGA line. (Technically it is possible to have an LDA line *and* a GGA line, in which case the LDA part of the GGA functional (if applicable) is replaced by what is specified by the LDA line.)

Apply States whether the functional defined on the pertaining line will be used self-consistently (in the SCF-potential), or only post-SCF, i.e. to evaluate the XC energy corresponding to the charge density. The value of apply must be **SCF** or **POSTSCF**. (**default=SCF**)

3.1.1 LDA/GGA/metaGGA

LDA Defines the LDA part of the XC functional and can be any of the following:

Xonly: The pure-exchange electron gas formula. Technically this is identical to the Xalpha form with a value 2/3 for the X-alpha parameter.

Xalpha: the scaled (parameterized) exchange-only formula. When this option is used you may (optionally) specify the X-alpha *parameter* by typing a numerical value after the string Xalpha (**Default: 0.7**).

VWN: the parametrization of electron gas data given by Vosko, Wilk and Nusair (ref[1], formula version V). Among the available LDA options this is the more advanced one, including correlation effects to a fair extent.

Stoll: For the VWN or GL variety of the LDA form you may include Stoll's correction[2] by typing Stoll on the same line, after the main LDA specification. You must not use Stoll's correction in combination with the Xonly or the Xalpha form for the Local Density functional.

GGA Specifies the GGA part of the XC Functional. It uses derivatives (gradients) of the charge density. Separate choices can be made for the GGA exchange correction and the GGA correlation correction respectively. Both specifications must be typed (if at all) on the same line, after the GGA subkey.

For the exchange part the options are:

- **Becke**: the gradient correction proposed in 1988 by Becke[3]

- **PW86x**: the correction advocated in 1986 by Perdew-Wang[4]

- **PW91x**: the exchange correction proposed in 1991 by Perdew-Wang[5]

- **mPWx**: the modified PW91 exchange correction proposed in 1998 by Adamo-Barone[6]

- **PBEx**: the exchange correction proposed in 1996 by Perdew-Burke-Ernzerhof[7]

[7] J.P. Perdew, K. Burke and M. Ernzerhof, *Generalized Gradient Approximation Made Simple.* Physical Review Letters 77, 3865 (1996) (https://doi.org/10.1103/PhysRevLett.77.3865).

- **HTBSx**: the HTBS exchange functional[8]

- **RPBEx**: the revised PBE exchange correction proposed in 1999 by Hammer-Hansen-Norskov[9]

- **revPBEx**: the revised PBE exchange correction proposed in 1998 by Zhang-Yang[10]

- **mPBEx**: the modified PBE exchange correction proposed in 2002 by Adamo-Barone[11]

- **OPTX**: the OPTX exchange correction proposed in 2001 by Handy-Cohen[12]

For the correlation part the options are:

- **Perdew**: the correlation term presented in 1986 by Perdew[13]

- **PBEc**: the correlation term presented in 1996 by Perdew-Burke-Ernzerhof[?]

- **PW91c**: the correlation correction of Perdew-Wang (1991), see[?][14][15]

- **LYP**: the Lee-Yang-Parr 1988 correlation correction[16]

Some GGA options define the exchange and correlation parts in one stroke. These are:

- **BP86**: this is equivalent to **Becke + Perdew** together

- **PW91**: this is equivalent to **pw91x + pw91c** together

- **mPW**: this is equivalent to **mPWx + pw91c** together

- **PBE**: this is equivalent to **PBEx + PBEc** together

- **HTBS**: this is equivalent to **HTBSx + PBEc** together

- **RPBE**: this is equivalent to **RPBEx + PBEc** together

- **revPBE**: this is equivalent to **revPBEx + PBEc** together

- **mPBE**: this is equivalent to **mPBEx + PBEc** together

- **BLYP**: this is equivalent to **Becke** (exchange) + **LYP** (correlation)

- **OLYP**: this is equivalent to **OPTX** (exchange) + **LYP** (correlation)

- **OPBE**: this is equivalent to **OPTX** (exchange) + **PBEc** (correlation)[17]

DiracGGA (Expert option!) This key handles which XC functional is used during the Dirac calculations of the reference atoms. A string is expected which is not restricted to names of GGAs but can be LDA-like functionals, too.

Note: In some cases using a GGA functional leads to slow convergence of matrix elements of the kinetic energy operator w. r. t. the `Accuracy` parameter. Then one can use the LDA potential for the calculation of the reference atom instead.

3.1. Density Functional (XC)

MetaGGA Key to select the evaluation of a meta-GGA. A byproduct of this option is that the bonding energies of all known functionals are printed (using the same density). Meta-GGA calculations can be time consuming, especially when active during the SCF.

Self consistency of the meta-GGA is implemented as suggested by Neuman, Nobes, and Handy[18].

The available functionals of this type are:

- **TPSS**: The 2003 meta-GGA[19]

- **M06L**: The meta-GGA as developed by the Minesota group[20]

- **revTPSS**: The 2009 revised meta-GGA[21]

- **MVS**: Functional by Sun-Perdew-Ruzsinszky[22]

- **MS0**: Functional by Sun et al.[23]

- **MS1**: Functional by Sun et al.[24]

- **MS2**: Functional by Sun et al.[?]

- **SCAN**: Functional by Sun et al.[25]

- **TASKxc**: by Aschebrock et al (https://journals.aps.org/prresearch/abstract/10.1103/PhysRevResearch.1.033082). Intended for band gaps and charge transfer systems.

- **TASKCC**: Functional by Lebeda et al.[35], improves TASKxc atomization energies

Note: For Meta-GGA XC functionals, it is recommended to use small or none *frozen core* (page 46) (the frozen orbitals are computed using LDA and not the selected Meta-GGA)

3.1.2 Dispersion Correction

BAND supports the new *D4(EEQ)* (page 17) as well as the older *D3 and D3-BJ* (page 17) dispersion corrections from the group of Stefan Grimme:

D4(EEQ)

Dispersion Grimme4 {s6=...} {s8=...} {a1=...} {a2=...} If `Dispersion Grimme4` is present in the `XC` block the D4(EEQ) dispersion correction (with the electronegativity equilibrium model) by the Grimme group[31][32] will be added to the total bonding energy, gradient and second derivatives, where applicable.

The D4(EEQ) model has four parameters: s_6, s_8, a_1 and a_2 and their value should depend on the XC functional used. For the following functionals the D4(EEQ) parameters are **predefined**: B1B95, B3LYP, B3PW91, B97-D, BLYP, BP86, CAM-B3LYP, HartreeFock, OLYP, OPBE, PBE, PBE0, PW6B95, REVPBE, RPBE, TPSS, TPSSH. For these functionals it is enough to specify `Dispersion Grimme4` in the input block. E.g.:

```
XC
  GGA BLYP
  Dispersion Grimme4
END
```

For all other functionals you should explicitly specify the D4(EEQ) parameters in the `Dispersion` key (otherwise the PBE parameters will be used). For example, for the PW91 functional you should use the following input:

```
XC
  GGA PW91
  Dispersion Grimme4 s6=1.0 s8=0.7728 a1=0.3958 a2=4.9341
END
```

The D4(EEQ) parameters for many functionals can be found in the supporting information of the following paper:[?].

D3 and D3-BJ

In BAND parameters for *Grimme3* and *Grimme3 BJDAMP* can be used according to version 3.1 (Rev. 1) of the coefficients, published on the Bonn Bonn website (https://www.chemie.uni-bonn.de/pctc/mulliken-center/software/dft-d3/dft-d3).

DISPERSION Grimme3 BJDAMP {PAR1=par1 PAR2=par2 PAR3=par3 PAR4=par4} If this key is present a dispersion correction (DFT-D3-BJ) by Grimme[27] will be added to the total bonding energy, gradient and second derivatives, where applicable. Parametrizations are implemented e.g. for B3LYP, TPSS, BP86, BLYP, PBE, PBEsol[26], and RPBE. For SCAN parameters from Ref.[28] are used. The parametrization has four parameters. One can override these using *PAR1=.. PAR2=..*, etc. In the table the relation is shown between the parameters and the real parameters in the dispersion correction.

DISPERSION Grimme3 {PAR1=par1 PAR2=par2 PAR3=par3} If this key is present a dispersion correction (DFT-D3) by Grimme[29] will be added to the total bonding energy, gradient and second derivatives, where applicable. Parametrizations are available e.g. for B3LYP, TPSS, BP86, BLYP, revPBE, PBE, PBEsol[?], and RPBE, and will be automatically set if one of these functionals is used. For SCAN parameters from Ref.[?] are used. For all other functionals, PBE-D3 parameters are used as default. You can explicitly specify the three parameters.

PAR1	s6
PAR2	sr,6
PAR3	s8

Dispersion {s6scaling RSCALE=r0scaling} If the DISPERSION keyword is present a dispersion correction will be added to the total bonding energy, where applicable. By default the correction of Grimme is applied[30]. The term is added to the bonding energies of all printed functionals, here the LDA and a couple of GGAs are meant. The global scaling factor, with which the correction is added, depends on the XC functional used for SCF but it can be modified using the *s6scaling* parameter. The following scaling factors are used (with the XC functional in parentheses): 1.20 (BLYP), 1.05 (BP), 0.75 (PBE), 1.05 (B3LYP). In all other cases a factor 1.0 is used unless modified via the s6scaling parameter. The van der Waals radii, used in this implementation, are hard-coded. However, it is possible to modify the global scaling parameter for them using the *RSCALE=r0scaling* argument. The default value is 1.1 as proposed by Grimme[?].

3.1.3 Model Potentials

Model Some functionals give only a potential and have no energy expression. We call such functionals model potentials. In BAND the following model potentials are available:

LB94 With this model the asymptotically correct potential of van Leeuwen and Baerends is invoked[33].

TB-mBJ This model potential can be used to correct for the band gap problem with GGAs for bulk systems[34]. This potential depends on a c-factor for which there is a density dependent automatic expression. However you can override the automatic value by specifying XC%TB_mBJCFactor cfac. In principle: the bigger the value the larger the gap. **KTB-mBJ/JTS-mTB-mBJ** are variations of **TB-mBJ**. The formula for C contains three parameters: A,B, and E. The logic is as follows

potential	A	B	E
TB-mBJ[?]	-0.012	1.023	0.5
KTB-mBJ[36]	0.267	0.656	1.0
JTS-mTB-mBJ[37]	0.4	1.0	0.5

The three parameters (A,B, and E) can be user-defined set as follows:

```
XC
   Model TB_mBJ
   TB_mBJAFactor valA
   TB_mBJBFactor valB
   TB_mBJEFactor valE
End
```

GLLB-SC This functional uses a model for the exchange response potential (based on J. Krieger, Y. Li and G. Iafrate response potential[39]) from which the derivative discontinuity follows[38]. This is an accurate functional for band gap predictions and Electric Field Gradient calculations. It is also a fast method and a very good compromise between accuracy and computational cost. This functional is composed of the GLLB exchange response potential and the PBESOL exchange hole and the correlation potential[?].

BGLLB-VWN This functional is a variation of the GLLB-SC functional using the B88 exchange hole potential and the VWN correlation potential. This functional gives good results for Group I-VII and II-VI semi conductors.

BGLLB-LYP This functional is a variation of the GLLB-SC functional using the B88 exchange hole potential and the LYP correlation potential. This functional gives good results for large band gap insulators.

One can change the K parameter for the GLLB functionals with the `GLLBKParameter` key:

```
XC
   Model [GLLB-SC|BGLLB-VWN|BGLLB-LYP]
   GLLBKParameter val
End
```

The default value is K=0.382 (value obtained from the electron gas model in the original publication).

3.1.4 Non-Collinear Approach

SpinOrbitMagnetization (**Default=CollinearZ**) Most XC functionals have as one ingredient the spin polarization. Normally the direction of the spin quantization axis is arbitrary and conveniently chosen to be the *z*-axis. However, in a *spin-orbit* (page 29) calculation the direction matters, and it is arbitrary to put the z-component of the magnetization vector into the XC functional. It is also possible to plug the size of the magnetization vector into the XC functional. This is called the non-collinear approach. There is also the exotic option to choose the quantization axis along the *x* or *y* axis. To summarize, the value **NonCollinear** invokes the non-collinear method. The other three option **CollinearX**, **CollinearY** and **CollinearZ** causes either the x, y, or z component to be used as spin polarization for the XC functional.

3.1.5 LibXC Library Integration

LibXC functional LibXC is a library of approximate XC functionals, see Ref.[40]. Version 5.1.2 of LibXC is used.. See the LibXC website for the complete list of functionals: http://www.tddft.org/programs/Libxc.

The following functionals can be evaluated with LibXC (incomplete list):

- **LDA:** LDA, PW92, TETER93

- **GGA:** AM05, BGCP, B97-GGA1, B97-K, BLYP, BP86, EDF1, GAM, HCTH-93, HCTH-120, HCTH-147, HCTH-407, HCTH-407P, HCTH-P14, PBEINT, HTBS, KT2, MOHLYP, MOHLYP2, MPBE, MPW,

[39] J.B. Krieger, Yan Li, G.J. Iafrate, *Derivation and application of an accurate Kohn-Sham potential with integer discontinuity*, Physics Letters A 8, 146 (1990) (https://doi.org/10.1016/0375-9601(90)90975-T)

[40] M.A.L. Marques, M.J.T. Oliveira, and T. Burnus, *Libxc: a library of exchange and correlation functionals for density functional theory*, Computer Physics Communications 183, 2272 (2012) (https://doi.org/10.1016/j.cpc.2012.05.007).

> N12, OLYP, PBE, PBEINT, PBESOL, PW91, Q2D, SOGGA, SOGGA11, TH-FL, TH-FC, TH-FCFO, TH-FCO, TH1, TH2, TH3, TH4, VV10, XLYP, XPBE, HLE16

- **MetaGGA:** M06-L, M11-L, MN12-L, MS0, MS1, MS2, MVS, PKZB, TPSS, HLE17, rSCAN, r2SCAN

- **Hybrids** (**only for non-periodic systems**): B1LYP, B1PW91, B1WC, B3LYP, B3LYP*, B3LYP5, B3LYP5, B3P86, B3PW91, B97, B97-1 B97-2, B97-3, BHANDH, BHANDHLYP, EDF2, MB3LYP-RC04, MPW1K, MPW1PW, MPW3LYP, MPW3PW, MPWLYP1M, O3LYP, OPBE, PBE0, PBE0-13, REVB3LYP, REVPBE, RPBE, SB98-1A, SB98-1B, SB98-1C, SB98-2A, SB98-2B, SB98-2C, SOGGA11-X, SSB, SSB-D, X3LYP

- **MetaHybrids** (**only for non-periodic systems**): B86B95, B88B95, BB1K, M05, M05-2X, M06, M06-2X, M06-HF, M08-HX, M08-SO, MPW1B95, MPWB1K, MS2H, MVSH, PW6B95, PW86B95, PWB6K, REVTPSSH, TPSSH, X1B95, XB1K

- **Range-separated** (**for periodic systems, only short range-separated functionals can be used**, see *Range-separated hybrid functionals* (page 21)): CAM-B3LYP, CAMY-B3LYP, HJS-PBE, HJS-PBESOL, HJS-B97X, HSE03, HSE06, LRC_WPBE, LRC_WPBEH, LCY-BLYP, LCY-PBE, M11, MN12-SX, N12-SX, TUNED-CAM-B3LYP, WB97, WB97X

Note that BAND can not calculate VV10 dependent LibXC functionals, like VV10, LC-VV10, B97M-V, WB97X-V.

Example usage for the MVS functional:

```
XC
  LibXC MVS
End
```

Notes:

- **All electron basis sets should be used** (see `CORE NONE` in section *Basis set* (page 46)).

- For periodic systems only short range-separated functionals can be used (see *Range-separated hybrid functionals* (page 21))

- In case of LibXC the output of the BAND calculation will give the reference for the used functional, see also the LibXC website http://www.tddft.org/programs/Libxc.

- Do not use any of the subkeys LDA, GGA, METAGGA, MODEL in combination with the subkey LIBXC.

- One can use the DISPERSION key icw LIBXC. For a selected number of functionals the optimized dispersion parameters will be used automatically, please check the output in that case.

- If you use a GGA functional via LibXC then BAND will calculate the XC potential, similar to what happens with the normal GGA key. For some GGA functionals, however, this gives a problem for certain elements (during the RADIAL part of the code). This has been tested for all elements and no such problems are observed for functionals in this white list: "AM05 BCGP BP86 HCTH-93 HCTH-120 HCTH-147 HCTH-407 HCTH-P14 PBEINT MPBE MPW PBE PBESOL PW91 SOGGA TH-FL XPBE HLE16". When using a GGA not in the white list BAND will automatically switch to another strategy. This means that core orbitals will no longer correspond to the GGA, and also the calculation will be less efficient. If that happens this warning will be printed: WARNING: requested libxc gga functional may give numerical problems for certain atom types (in the RADIAL section))

3.1.6 Hartree-Fock

Pure Hartree-Fock is triggered by the key

```
XC
    HartreeFock true
End
```

- The Hartree-Fock exchange matrix is calculated through a procedure known as Resolution of the Identity (RI). See *RIHartreeFock* (page 68) key.

There are some shortcomings to this option

- It does not work with a frozen core

- There are no gradients available

- Does not work for periodic systems

3.1.7 Range-separated hybrid functionals

Short range-separated hybrid functionals, like the **HSE03** functional[41], can be useful for prediction of more accurate band gaps compared to GGAs. These must be specified via the *LibXC* (page 19) key

```
XC
    LibXC functional {omega=value}
End
```

functional The functional to be used. (Incomplete) list of available functionals: **HSE06**, **HSE03**, **HJS-B97X**, **HJS-PBE** and **HJS-PBESOL** (See the LibXC website (http://www.tddft.org/programs/octopus/wiki/index.php/Libxc_functionals) for a complete list of available functionals).

omega *Optional*. You can optionally specify the switching parameter omega of the range-separated hybrid. Only possible for the **HSE03** and **HSE06** functionals (See[?]).

Notes:

- Hybrid functionals can only be used in combination with all-electron basis sets (see `CORE NONE` in section *Basis set* (page 46)).

- The Hartree-Fock exchange matrix is calculated through a procedure known as Resolution of the Identity (RI). See *RIHartreeFock* (page 68) key.

- Regular hybrids (such as B3LYP) and long range-separated hybrids (such as CAM-B3LYP) **cannot** be used in periodic boundary conditions calculations (they can only be used for non-periodic systems).

- There is some confusion in the scientific literature about the value of the switching parameter ω for the HSE functionals. In LibXC, and therefore in BAND, the HSE03 functional uses $\omega = 0.106066$ while the HSE06 functional uses $\omega = 0.11$.

Usage example:

```
XC
    LibXC HSE06 omega=0.1
End
```

---

[41] J. Heyd, G.E. Scuseria and M. Ernzerhof, *Hybrid functionals based on a screened Coulomb potential*, J. Chem. Phys. 118, 8207 (2003) (https://doi.org/10.1063/1.1564060).

3.1.8 Double hybrids, MP2 and RPA

Starting from AMS2023, Many-body perturbation theory functionals (double hybrids, MP2, and RPA) as implemented in ADF can also be used in the BAND engine for the molecular (non-periodic) case, see the ADF documentation for an overview over the implemented functionals.

- RPA and double hybrids

Generally, BAND supports the same MBPT functionality as ADF. However, in Band, MP2, RPA, and double hybrids can not be used icw spin-orbit coupling.

It is recommended to adjust the **Basis** key inside the **Dependency** block and the **DependencyThreshold** inside the **RIHartreeFock** block. Typically, MBPT calculations require a large basis set (See the MBPT documentation inside ADF), ideally of quadruple-zeta quality or larger. In this case, the following settings are recommended.

Usage example:

```
XC
   DoubleHybrid B2PLYP
End

Dependency
   AllowBasisDependency True
   Basis 1e-4
End

Softconfinement
   Quality Excellent
End

RIHartreeFock
   DependencyThreshold 1e-3
End
```

3.1.9 Defaults and special cases

- If the `XC` key is not used, the program will apply only the Local Density Approximation (no GGA terms). The chosen LDA form is then VWN.

- If only a GGA part is specified, omitting the *LDA* subkey, the LDA part defaults to VWN, except when the LYP correlation correction is used: in that case the LDA default is Xonly: pure exchange.

- The reason for this is that the LYP formulas assume the pure-exchange LDA form, while for instance the Perdew-86 correlation correction is a correction to a *correlated* LDA form. The precise form of this correlated LDA form assumed in the Perdew-86 correlation correction is not available as an option in ADF but the VWN formulas are fairly close to it.

- Be aware that typing only the subkey *LDA*, without an argument, will activate the VWN form (also if LYP is specified in the GGA part).

3.1.10 GGA+U

A special way to treat correlation is with so-called LDA+U, or GGA+U calculations. It is intended to solve the band gap problem of traditional DFT, the problem being an underestimation of band gaps for transition-metal complexes. A Hubbard like term is added to the normal Hamiltonian, to model on-site interactions. In its very simplest form it depends on only one parameter, U, and this is the way it has been implemented in BAND. The energy expression is equation (11) in the work of Cococcioni[43]. See also the review article[42].

```
HubbardU

An example to apply LDA+U to the d-orbitals of NiO looks like:

```
...
Atoms
   Ni 0.000  0.000  0.000
   O 2.085  2.085  2.085
End
...

...
HubbardU
   printOccupations true
   Atom    element=Ni UValue=0.3  lValue=2
End
...
```

It is also possible to specify U per region.

Example: Fixing the Band gap of NiO with GGA+U (page 194)

3.1.11 OEP

(Expert options) When you are using a meta-GGA you are by default using a generalized Kohn-Sham method. However, it is possible to calculate a local potential, as is required for a strict Kohn-Sham calculation, via OEP, (see[44]).

The main options are controlled with the `MetaGGA` subkey of the XC block if `OEP` is present.

```
XC
   [...]
   MetaGGA GGA OEP {approximation} {Fit} {Potential}
   [...]
End
```

GGA specifies the name of the used meta-GGA. In combination with OEP only **PBE**, **TPSS**, **MVS**, **MS0**, **MS1**, **MS2**, and **SCAN** can be used!

approximation (**Default: KLI**) There are three flavors to approximate the OEP: **KLI**, **Slater**, and **ELP**

Fit By adding the string **Fit** on this line, one uses the fitted density instead of the exact density for the evaluation.

Potential If not specified, only the tau-dependent part of the OEP is evaluated and used. By adding the string **Potential** in addition the tau-independent part is added to the XC potential. (This is needed e.g. for plotting the 'vxc')

With the following subkeys of the `XC` blockkey you have extra control over the iterative OEP evaluation:

MGGAOEPMaxIter (**Default: 30**) defines the maximum number of cycles for the iterative OEP evaluation.

MGGAOEPConvergence (**Default: 1E-6**) defines convergence criterion for OEP evaluation.

MGGAOEPWaitIter (**Default: 0**) defines the number of SCF cycles with the regular meta-GGA before switching to the OEP scheme.

MGGAOEPMaxAbortIter (**Default: 0**) defines number of cycles for which the error is allowed to increase before the calculation is aborted. Here, zero means: do never abort.

MGGAOEPMaxErrorIncrease (**Default: 0.0**) defines the maximum rate of increasing error before the calculation is aborted. Here, zero means: do never abort.

An example for an OEP metaGGA calculation

```
XC
   MetaGGA MVS OEP
End
```

Note that a very fine Becke grid is needed.

```
BeckeGrid
   Quality USER
   UserRadMulFactor 20.0
   UserCoreL 11
   UserInter1L 13
   UserInter2L 21
   UserExterL 31
   UserExterLBoost 35
 End
```

Note also: the gaps are typically not closer to experiment, and the calculations are more expensive. This option is mainly about academic interest.

3.1.12 DFT-1/2

The DFT-1/2 method due to Slater has been extended by Ferreira ([PRB,78,125116,2008](https://doi.org/10.1103/PhysRevB.78.125116)) to address the band gap problem. DFT-1/2 can be used in combination with any XC functional (this method is also referred to as LDA-1/2 or GGA-1/2, depending on the functional used).

The physical picture is that the hole is localized having substantial self energy. Adding an electron to the solid is assumed to go to a very delocalized state with little or no self energy. The method amounts to adding attractive spherical potentials at atomic sites and optimizing the screening parameter for maximal band gap, and can be used on top of any functional, relativistic option and spin option. From this viewpoint the only freedom in the method is the list of active atom types, the ones for which we will add the potential and optimize the gap. The l-dependent potential option from Ferreira is currently not supported.

The simplest approach is to optimize all the atom types. However, one can also look at the character of the top of the valence band, and determine which atoms are contributing to the PDOS there. This can be done by hand by using the bandstructure GUI module. In band there is an option to analyze this automatically, see the Prepare=true sub option.

Example: DFT-1/2 method for Silicon (page 199)

```
XC
   DFTHalf
      ActiveAtomType
         AtomType string
         IonicCharge float
         ScreeningCutOffs float_list
      End
      Enabled Yes/No
      Prepare Yes/No
      SelfConsistent Yes/No
   End
End
```

XC

    DFTHalf

        Type Block

        Description DFT-1/2 method for band gaps. See PRB vol 78,125116 2008. This method can be used in combination with any functional. For each active atom type (see ActiveAtomType) Band will perform SCF calculations at different screening cut-off values (see ScreeningCutOffs) and pick the cut-off value that maximizes the band gap. If multiple atom types are active, the screening cut-off optimizations are done one type at the time (in the same order as the ActiveAtomType blocks appear in the input).

    ActiveAtomType

        Type Block

        Recurring True

        Description Use the DFT-1/2 method for the atom-type specified in this block.

    AtomType

        Type String

        Description Atom-type to use. You can activate all atom-types by specifying 'All'.

    IonicCharge

Type Float

Default value 0.5

Description The amount of charge to be removed from the atomic HOMO.

ScreeningCutOffs

Type Float List

Default value [0.0, 1.0, 2.0, 3.0, 4.0, 5.0]

Unit Bohr

Description List of screening cut-offs (to screen the asymptotic IonicCharge/r potential). Band will loop over these values and find the cut-off that maximizes the band-gap. If only one number is provided, Band will simply use that value.

Enabled

Type Bool

Default value No

GUI name Use method

Description Whether the DFT-1/2 method will be used.

Prepare

Type Bool

Default value No

Description Analyze the band structure to determine reasonable settings for an DFT-1/2 calculation. If this is possible the list of active atom types is written to the output. This can be used in a next run as the values for ActiveAtomType. The DFTHalf%Enabled key should be set to false

SelfConsistent

Type Bool

Default value Yes

Description Apply the extra potential during the SCF, or only afterwards. Applying DFT-1/2 only post SCF increases the band gap, compared to the self-consistent one.

Here are some results showing that LDA-1/2 can work quite well, but that the TB-mBJ functional works better for this set.
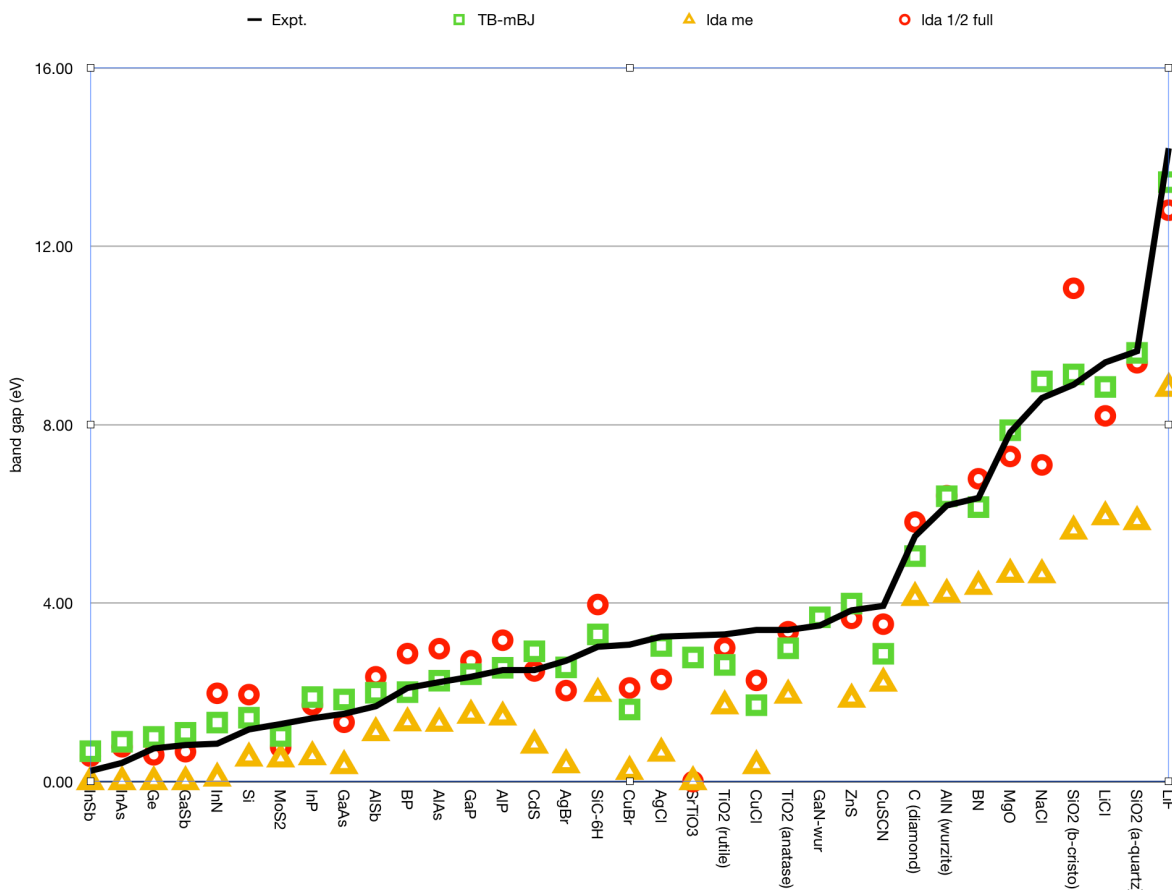

3.2 Relativistic Effects and Spin

3.2.1 Spin polarization

By default Band calculations are spin-restricted. You can instruct Band to perform a spin-unrestricted via the `Unrestricted` key:

```
Unrestricted Yes/No
```

Unrestricted

>   **Type** Bool
>
>   **Default value** No
>
>   **Description** Controls whether Band should perform a spin-unrestricted calculation. Spin-unrestricted calculations are computationally roughly twice as expensive as spin-restricted.

The orbitals are occupied according to the aufbau principle.

If you want to enforce a specific spin-polarization (instead of occupying according to the aufbau principle) you can use the `EnforcedSpinPolarization` key:

```
EnforcedSpinPolarization float
```

EnforcedSpinPolarization

> **Type** Float
>
> **GUI name** Spin polarization
>
> **Description** Enforce a specific spin-polarization instead of occupying according to the aufbau principle. The spin-polarization is the difference between the number of alpha and beta electron.
>
> Thus, a value of 1 means that there is one more alpha electron than beta electrons.
>
> The number may be anything, including zero, which may be of interest when searching for a spin-flipped pair, that may otherwise end up in the (more stable) parallel solution.

3.2.2 Relativistic Effects

Relativistic effects are treated with the accurate and efficient ZORA approach[1][2], controlled by the `Relativity` keyword. Relativistic effects are negligible for light atoms, but grow to dramatic changes for heavy elements. A rule of thumb is: Relativistic effects are quite small for elements of row 4, but very large for row 6 elements (and later).

```
Relativity
   Level [None | Scalar | Spin-Orbit]
End
```

Relativity

> **Type** Block
>
> **Description** Options for relativistic effects.

> **Level**
>
> > **Type** Multiple Choice
> >
> > **Default value** Scalar
> >
> > **Options** [None, Scalar, Spin-Orbit]
> >
> > **GUI name** Relativity (ZORA)
> >
> > **Description** None: No relativistic effects.
> >
> > Scalar: Scalar relativistic ZORA. This option comes at very little cost.
> >
> > SpinOrbit: Spin-orbit coupled ZORA. This is the best level of theory, but it is (4-8 times) more expensive than a normal calculation. Spin-orbit effects are generally quite small, unless there are very heavy atoms in your system, especially with p valence electrons (like Pb).
> >
> > See also the SpinOrbitMagnetization key.

See also the *SpinOrbitMagnetization* (page 19) key.

3.3 Solvation

Band offers two implicit solvent models, COSMO and SM12.

3.3.1 COSMO: Conductor like Screening Model and the Solvation-key

You can study chemistry in solution, as contrasted to the gas phase, with the implementation in BAND of the Conductor like Screening Model (COSMO) of solvation[1].

In the COSMO model all solvents are roughly the same, and approximated by an enveloping metal sheet. One explicit dependency on the solvent is that the solvation energy is scaled by

$$f(\epsilon) = \frac{\epsilon - 1}{\epsilon + \chi}$$

and this depends on the dielectric constant of the solvent, and an empirical factor χ. The other is that the shape of the surface is influenced by the *Rad* parameter, see below.

The solvent information is specified in the `solvent` key of the `solvation` block. The simplest option is to use one of the pre-defined solvents:

```
Solvation
   Enabled Yes/No
   Solvent
      Name [...]
   End
End
```

Solvation

> **Type** Block
>
> **Description** Options for the COSMO (Conductor like Screening Model) solvation model.

Enabled

> **Type** Bool
>
> **Default value** No
>
> **GUI name** Include COSMO solvation
>
> **Description** Use the Conductor like Screening Model (COSMO) to include solvent effects.

Solvent

> **Type** Block
>
> **Description** Solvent details

Name

> > **Type** Multiple Choice
> >
> > **Default value** Water
> >
> > **Options** [AceticAcid, Acetone, Acetonitrile, Ammonia, Aniline, Benzene, BenzylAlcohol, Bromoform, Butanol, isoButanol, tertButanol, CarbonDisulfide, CarbonTetrachloride, Chloroform, Cyclohexane, Cyclohexanone, Dichlorobenzene, DiethylEther, Dioxane, DMFA,

DMSO, Ethanol, EthylAcetate, Dichloroethane, EthyleneGlycol, Formamide, FormicAcid, Glycerol, HexamethylPhosphoramide, Hexane, Hydrazine, Methanol, MethylEthylKetone, Dichloromethane, Methylformamide, Methypyrrolidinone, Nitrobenzene, Nitrogen, Nitromethane, PhosphorylChloride, IsoPropanol, Pyridine, Sulfolane, Tetrahydrofuran, Toluene, Triethylamine, TrifluoroaceticAcid, Water]

GUI name Solvent

Description Name of a pre-defined solvent. A solvent is characterized by the dielectric constant (Eps) and the solvent radius (Rad).

This is the list of possible solvents and their corresponding `Eps` and `Rad` values:

Solvent Name	Formula	Eps	Rad
AceticAcid	CH3COOH	6.19	2.83
Acetone	CH3COCH3	20.7	3.08
Acetonitrile	CH3CN	37.5	2.76
Ammonia	NH3	16.9	2.24
Aniline	C6H5NH2	6.8	3.31
Benzene	C6H6	2.3	3.28
BenzylAlcohol	C6H5CH2OH	13.1	3.45
Bromoform	CHBr3	4.3	3.26
Butanol	C4H9OH	17.5	3.31
isoButanol	(CH3)2CHCH2OH	17.9	3.33
tertButanol	(CH3)3COH	12.4	3.35
CarbonDisulfide	CS2	2.6	2.88
CarbonTetrachloride	CCl4	2.2	3.37
Chloroform	CHCl3	4.8	3.17
Cyclohexane	C6H12	2	3.5
Cyclohexanone	C6H10O	15	3.46
Dichlorobenzene	C6H4Cl2	9.8	3.54
DiethylEther	(CH3CH2)2O	4.34	3.46
Dioxane	C4H8O2	2.2	3.24
DMFA	(CH3)2NCHO	37	3.13
DMSO	(CH3)2SO	46.7	3.04
Ethanol	CH3CH2OH	24.55	2.85
EthylAcetate	CH3COOCH2CH3	6.02	3.39
Dichloroethane	ClCH2CH2Cl	10.66	3.15
EthyleneGlycol	HOCH2CH2OH	37.7	2.81
Formamide	HCONH2	109.5	2.51
FormicAcid	HCOOH	58.5	2.47
Glycerol	C3H8O3	42.5	3.07
HexamethylPhosphoramide	C6H18N3OP	43.3	4.1
Hexane	C6H14	1.88	3.74
Hydrazine	N2H4	51.7	2.33
Methanol	CH3OH	32.6	2.53
MethylEthylKetone	CH3CH2COCH3	18.5	3.3
Dichloromethane	CH2Cl2	8.9	2.94
Methylformamide	HCONHCH3	182.4	2.86
Methypyrrolidinone	C5H9NO	33	3.36
Nitrobenzene	C6H5NO2	34.8	3.44
Nitrogen	N2	1.45	2.36
Nitromethane	CH3NO2	35.87	2.77

PhosphorylChloride	POCl3	13.9	3.33
IsoPropanol	(CH3)2CHOH	19.9	3.12
Pyridine	C5H5N	12.4	3.18
Sulfolane	C4H8SO2	43.3	3.35
Tetrahydrofuran	C4H8O	7.58	3.18
Toluene	C6H5CH3	2.38	3.48
Triethylamine	(CH3CH2)3N	2.44	3.81
TrifluoroaceticAcid	CF3COOH	8.55	3.12
Water	H2O	78.39	1.93

Several other options can be defined in the `Solvation` block:

```
Solvation
   CVec [EXACT | FITPOT]
   Charge
      Conv float
      Corr Yes/No
      Iter integer
      Method [CONJ | INVER]
   End
   Enabled Yes/No
   Radii # Non-standard block. See details.
      ...
   End
   SCF [VAR | PERT | NONE]
   Solvent
      Del float
      Emp float
      Eps float
      Name [...]
      Rad float
   End
   Surf [Delley | Wsurf | Asurf | Esurf | Klamt]
End
```

Solvation

> **Type** Block
>
> **Description** Options for the COSMO (Conductor like Screening Model) solvation model.

CVec

> **Type** Multiple Choice
>
> **Default value** EXACT
>
> **Options** [EXACT, FITPOT]
>
> **GUI name** Calculate Coulomb interaction
>
> **Description** Choose how to calculate the Coulomb interaction matrix between the molecule and the point charges on the surface:
>
> - EXACT: use exact density, and integrate against the potential of the point charges. This may have inaccuracies when integration points are close to the point charges.
>
> - FITPOT: evaluate the molecular potential at the positions of the point charges, and multiply with these charges.

Charge

>   **Type** Block
>

>   **Default value** No
>
>   **GUI name** Include COSMO solvation
>
>   **Description** Use the Conductor like Screening Model (COSMO) to include solvent effects.

Radii

>   **Type** Non-standard block
>
>   **Description** The values are the radii of the atomic spheres. If not specified the default values are those by Allinge. Format: 'AtomType value'. e.g.: 'H 0.7'

SCF

>   **Type** Multiple Choice
>
>   **Default value** VAR
>
>   **Options** [VAR, PERT, NONE]

GUI name Handle charges

Description Determine the point charges either Variational (VAR) or after the SCF as a Perturbation (PERT).

Solvent

    Type Block

    Description Solvent details

    Del

        Type Float

        Description Del is the value of Klamt's delta_sol parameter, only relevant in case of Klamt surface.

    Emp

        Type Float

        Description Emp is the empirical scaling factor x for the energy scaling.

    Eps

        Type Float

        Description User-defined dielectric constant of the solvent (overrides the Eps value of the solvent defined in 'Name')

    Name

        Type Multiple Choice

        Default value Water

        Options [AceticAcid, Acetone, Acetonitrile, Ammonia, Aniline, Benzene, BenzylAlcohol, Bromoform, Butanol, isoButanol, tertButanol, CarbonDisulfide, CarbonTetrachloride, Chloroform, Cyclohexane, Cyclohexanone, Dichlorobenzene, DiethylEther, Dioxane, DMFA, DMSO, Ethanol, EthylAcetate, Dichloroethane, EthyleneGlycol, Formamide, FormicAcid, Glycerol, HexamethylPhosphoramide, Hexane, Hydrazine, Methanol, MethylEthylKetone, Dichloromethane, Methylformamide, Methypyrrolidinone, Nitrobenzene, Nitrogen, Nitromethane, PhosphorylChloride, IsoPropanol, Pyridine, Sulfolane, Tetrahydrofuran, Toluene, Triethylamine, TrifluoroaceticAcid, Water]

        GUI name Solvent

        Description Name of a pre-defined solvent. A solvent is characterized by the dielectric constant (Eps) and the solvent radius (Rad).

    Rad

        Type Float

        Unit Angstrom

        Description User-defined radius of the solvent molecule (overrides the Rad value of the solvent defined in 'Name').

    Surf

        Type Multiple Choice

        Default value Delley

        Options [Delley, Wsurf, Asurf, Esurf, Klamt]

GUI name Surface type

Description Within the COSMO model the molecule is contained in a molecule shaped cavity.

Select one of the following surfaces to define the cavity:

- Wsurf: Van der Waals surface - Asurf: solvent accessible surface - Esurf: solvent excluding surface - Klamt: Klamt surface - Delley: Delley surface.

3.3.2 Additional keys for periodic systems

For the simulation of periodic structures ICW solvation, you may specify the following options:

```
PeriodicSolvation
   RemovePointsWithNegativeZ Yes/No
   NStar integer
End
```

PeriodicSolvation

> **Type** Block
>
> **Description** Additional options for simulations of periodic structures with solvation.

RemovePointsWithNegativeZ

> **Type** Bool
>
> **Default value** No
>
> **GUI name** Only above slab
>
> **Description** Whether the COSMO surface is constructed on both sides of a surface.
>
> If one is only interested in the solvation effect on the upper side of a surface (in the Z direction), then this option should be set to 'True'

NStar

> **Type** Integer
>
> **Default value** 4
>
> **Description** This option, expecting an integer number (>2), handles the accuracy for the construction of the COMSO surface. The larger the given number the more accurate the construction.

General remarks: The accuracy of the result and the calculation time is influenced by the screening radius `SCREEN-ING%RMADEL` (see *Screening* (page 91) block). If the calculation does take too long, defining a smaller radius does help. **But:** too small radii, especially smaller than the lattice constants, will give unphysical results.

3.3.3 SM12: Solvation Model 12

Continuum solvation can be done with the Minnesota's Solvation Model 12 (SM12) (JCTC,9,609,2013 (https://pubs.acs.org/doi/10.1021/ct300900e)). Details on the implementation of SM12 in ADF can be found in Ref. (JCTC,12,4033,2016 (https://pubs.acs.org/doi/10.1021/acs.jctc.6b00410)). The energetics of solvation is calculated using:

$$\Delta G_S^{\otimes} = \Delta E_E + G_P + G_{CDS} + \Delta G_N + \Delta G_{conc}^{\otimes}$$

where the symbol $\otimes$ denotes an arbitrary choice of standard states, ΔE_E is the change in the solute's internal electronic energy in transferring from the gas phase to the liquid phase at the same geometry, G_P is the polarization free energy

of the solute–solvent system when the solute is inserted, G_{CDS} is the component of the free energy that is nominally associated with cavitation, dispersion, and solvent structure, ΔG_N is the change in ΔG_S^0 due to a change in nuclear coordinates, and $\Delta G_{conc}^{\otimes}$ accounts for the difference in concentrations, if any, in the gas-phase standard state and the solution-phase one. In case of 1 M concentration in both solution and gas, then $\Delta G_S^{\otimes} = 0$ kcal/mol, which yields ΔG_S^*. If the same geometry is used in solution and gas phase calculation, then ΔG_N is zero.

SM12 makes use of the Generalized Born approximation to calculate the bulk electrostatic contribution. This is comprised of several terms that are together known as the ENP (Electronic, Nuclear, and Polarization) term G_P. The SM12 model in Band uses CM5. CM5 is a class 4 charge model, making use of both empirical and density related terms. It is comprised of Hirshfeld charges, a simple bond order calculation, atomic distances, and atom specific parameters. The covalent radii utilized are based on the atomic covalent radius from the Handbook of Chemistry and Physics. The Coulomb integral is described with the use of an approximation from Still et al.. Several parameters go into describing this, which include: inter atomic distance, an empirical Born constant, and the Born area, which is calculated with the Analytical Surface Area (ASA) algorithm. The Born area is calculated using Legendre-Gauss quadrature from the atomic radii to a sphere that encapsulates the entire molecule.

The ASA algorithm is also used to calculate the solvent accessible surface area (SASA), which is computed within the CDS (Cavitation, Dispersion, Solvation) term of SM12. The CDS term depends on three terms:

- SASA (ASA Algorithm)

- Atomic surface tension

- Macroscopic surface tension

Atomic surface tension is based on atom-atom distances and the solvent. Macroscopic surface tension is solvent specific. The SM12 implementation in Band reports energies in an atom specific way. You can attribute exact CDS and polarization energies to each atom in your solute. The parameters for SM12 are derived to explicitly incorporate organic elements (N, C, O, F, Si, P, S, Cl, Br, I), with less emphasis on non-organics. Also, while most solvents have a generic atomic surface tension reliance for atoms, water has it's own explicit set of parameters to better describe it.

Input

The minimal input for the SM12 method is the following:

```
SolvationSM12
   Enabled Yes/No
   Solv [...]
End
```

SolvationSM12

        Type Block

        Description Options for Solvation Model 12 (SM12).

    Enabled

        Type Bool

        Default value No

        GUI name Include SM12 solvation

        Description Whether to use the Solvation Model 12 (SM12) in the calculation.

    Solv

        Type Multiple Choice

        Default value WATER

Options [ACETICACID, ACETONITRILE, ACETOPHENONE, ANILINE, ANISOLE, BEN-
ZENE, BENZONITRILE, BENZYLALCOHOL, BROMOBENZENE, BROMOETHANE,

3.4 Electric and Magnetic Fields

3.4.1 Electric Field

The external electric field is handled at the AMS level, see the documentation there.

The effect of a magnetic filed can be **approximated** by the following potential: $\mu_B \vec{\sigma}_i \vec{B}$, where μ_B is the Bohr magneton, $\vec{\sigma}_i$ are the Pauli matrices and $\vec{B}$ is the magnetic field. For *Spin-unrestricted collinear* (page 28) calculations, the spin is assumed to be aligned with the z-axis.

3.4.2 Magnetic Field

```
BField
   Bx float
   By float
   Bz float
   Dipole Yes/No
   DipoleAtom integer
   Method [NR_SDOTB | NR_LDOTB | NR_SDOTB_LDOTB]
   Unit [tesla | a.u.]
End
```

BField

> **Type** Block
>
> **Description** The effect of a magnetic filed can be approximated by the following potential: mu * sigma_i * B, where mu is the Bohr magneton, sigma_i are the Pauli matrices and B is the magnetic field

> **Bx**
>

> >
> > **Unit** Tesla
> >
> > **Description** Value of the z component of the BField

> **Dipole**
>
> > **Type** Bool
> >
> > **Default value** No
> >
> > **GUI name** Bfield is: Atomic dipole
> >
> > **Description** Use an atomic dipole as magnetic field instead of a uniform magnetic field.

> **DipoleAtom**
>
> > **Type** Integer
> >
> > **Default value** 1
> >
> > **GUI name** on atom number

Description Atom on which the magnetic dipole should be centered (if using the dipole option)

Method

    Type Multiple Choice

    Default value NR_SDOTB

    Options [NR_SDOTB, NR_LDOTB, NR_SDOTB_LDOTB]

    Description There are two terms coupling to an external magnetic field.

        One is the intrinsic spin of the electron, called S-dot-B, the other one is the orbital momentum call L-dot-B.

        The L.B is implemented non-relativistically, using GIAOs in the case of a homogeneous magnetic field (not for the dipole case).

Unit

    Type Multiple Choice

    Default value tesla

    Options [tesla, a.u.]

    Description Unit of magnetic filed. The a.u. is the SI version of a.u.

3.4.3 Atom-wise fuzzy potential

```
FuzzyPotential # Non-standard block. See details.
   ...
End
```

FuzzyPotential

    Type Non-standard block

    Description Atomic (fuzzy cell) based, external, electric potential. See example.

Example:

```
FuzzyPotential
   scale $scale
   a1 v1   ! atom with index a1 gets potential coefficient v1 (a.u.)
   a2 v2   ! atom a2 gets potential v2
   ...
End
```

scale Overall scaling factor to be applied.

If an atom is not in the list it gets a coefficient of zero. The potential of an atom is its number (v_i) as specified on input times its fuzzy cell

$$V(r) = \sum_i^{\text{atoms}} v_i \mathcal{P}_{i,U}(r)$$

using the same partition function $\mathcal{P}$ as for the *BeckeGrid* (page 62). A partition function (or fuzzy cell) of an atom is close to one in the neighborhood of this atom.

The sign convention is: negative is favorable for electrons. (Unit: a.u.)

3.5 Nuclear Model

```
NuclearModel [PointCharge | Gaussian | Uniform]
```

NuclearModel

> **Type** Multiple Choice
>
> **Default value** PointCharge
>
> **Options** [PointCharge, Gaussian, Uniform]
>
> **Description** Specify what model to use for the nucleus.
>
>> For the Gaussian model the nuclear radius is calculated according to the work of Visscher and Dyall (L. Visscher, and K.G. Dyall, Dirac-Fock atomic electronic structure calculations using different nuclear charge distributions, Atomic Data and Nuclear Data Tables 67, 207 (1997))

ACCURACY AND EFFICIENCY

Given a *Model Hamiltonian* (page 13), the most important aspects determining the accuracy of a Band calculation are:

- *Basis set* (page 46)
- *K-Space* (page 57)

Also important, but to a lesser degree, are the following aspects:

- *Numerical Integration (BeckeGrid)* (page 62)
- *Density fitting (ZlmFit)* (page 65)
- *Basis-set confinement (SoftConfinement)* (page 54)
- *SCF convergence (Convergence)* (page 72)
- *Hartree–Fock Resolution of the Identity (RIHartreeFock)* (page 68) (only for hybrid functionals)
- *For Many-body-perturbation theory (MBPT) options* (page 84) (only for MBPT calculations)

The CPU time and memory requirements strongly depend on these options, as does the accuracy of the results.

General NumericalQuality

A simple way of tweaking the accuracy of the calculation is via the **NumericalQuality** key. This sets the quality of several technical aspects of a Band calculation (with the notable exception of the *basis set* (page 46))

```
NumericalQuality [Basic | Normal | Good | VeryGood | Excellent]
```

NumericalQuality

> **Type** Multiple Choice
>
> **Default value** Normal
>
> **Options** [Basic, Normal, Good, VeryGood, Excellent]
>
> **Description** Set the quality of several important technical aspects of a BAND calculation (with the notable exception of the basis set). It sets the quality of: BeckeGrid (numerical integration), ZlmFit (density fitting), KSpace (reciprocal space integration), and SoftConfinement (basis set confinement). Note: the quality defined in the block of a specific technical aspects supersedes the value defined in NumericalQuality (e.g. if I specify 'NumericalQuality Basic' and 'BeckeGrid%Quality Good', the quality of the BeckeGrid will be 'Good')

4.1 Basis set

Band represents the single-determinant electronic wave functions as a linear combinations of atom-centered basis functions (the basis set). See also: Wikipedia page on Basis Sets (https://en.wikipedia.org/wiki/Basis_set_(chemistry)).

The basis sets in Band consists of **NAOs** (Numerical Atomic Orbitals, obtained by solving numerically the Kohn-Sham equations for the isolated spherical atoms) augmented by a set of **STOs** (Slater Type Orbitals).

The choice of basis set is very important, as it influences heavily the accuracy, the CPU time and the memory usage of the calculation. Band comes with 6 predefined types of basis sets: **SZ**, **DZ**, **DZP**, **TZP**, **TZ2P**, **QZ4P** (SZ: Single Zeta, DZ: Double Zeta, DZP: Double Zeta + Polarization, TZP: Triple Zeta + Polarization, TZ2P: Triple Zeta + Double Polarization, QZ4P: Quadruple Zeta + Quadruple Polarization). See the sections *Which basis set should I use?* (page 47) and *Available Basis Sets* (page 50) for more details.

To speed up the calculation, Band can use the **frozen core approximation** in which core orbitals are kept frozen during the SCF procedure (and the valence orbitals are orthogonalized against the frozen orbitals). One can run an **all electron** calculation by specifying `Core None` in the Basis input block. Note: some features, such as *Hybrid functionals* (page 21), are incompatible with the frozen-core approximation, and require an all electron (i.e. `Core None`) basis set.

4.1.1 Basis input block

You can specify which basis set to use in the `Basis` input block.

```
Basis
   Type [SZ | DZ | DZP | TZP | TZ2P | QZ4P | STO/TZ2P | STO/SZ | STO/DZ | STO/DZP |↵
→STO/QZ4P |
         CORR/QZ6P | CORR/TZ3P | GTO/CC-PV5Z | GTO/DEF2-QZVPPD | GTO/CC-PV6Z | GTO/CC-
→PVQZ |
         GTO/CC-PVTZ | GTO/CC-PVDZ | GTO/DEF2-SVP | GTO/DEF2-TZVP | GTO/DEF2-TZVPP |↵
→GTO/DEF2-QZVP |
         GTO/AUG-CC-PVDZ | GTO/AUG-CC-PVTZ]
   Core [None | Small | Medium | Large]
End
```

Basis

>> **Type** Block

>> **Description** Definition of the basis set

> **Type**

>> **Type** Multiple Choice

>> **Default value** DZ

>> **Options** [SZ, DZ, DZP, TZP, TZ2P, QZ4P, STO/TZ2P, STO/SZ, STO/DZ, STO/DZP, STO/QZ4P, CORR/QZ6P, CORR/TZ3P, GTO/CC-PV5Z, GTO/DEF2-QZVPPD, GTO/CC-PV6Z, GTO/CC-PVQZ, GTO/CC-PVTZ, GTO/CC-PVDZ, GTO/DEF2-SVP, GTO/DEF2-TZVP, GTO/DEF2-TZVPP, GTO/DEF2-QZVP, GTO/AUG-CC-PVDZ, GTO/AUG-CC-PVTZ]

>> **GUI name** Basis set

>> **Description** Select the basis set to use.

>> SZ : Single Z DZ : Double Z DZP : Double Z, 1 polarization function TZP : Triple Z, 1 polarization function TZ2P : Triple Z, 2 polarization functions QZ4P : Quadruple Z, 4 polarization function

The basis set chosen will apply to all atoms in your structure. If a matching basis is not found a better type might be used.

Core

> **Type** Multiple Choice
>
> **Default value** Large
>
> **Options** [None, Small, Medium, Large]
>
> **GUI name** Frozen core
>
> **Description** Select the size of the frozen core you want to use.
>
> Small, Medium, and Large will be interpreted within the basis sets available (of the selected quality), and might refer to the same core in some cases.

4.1.2 Which basis set should I use?

The hierarchy of basis sets, from the smallest and least accurate (SZ) to the largest and most accurate (QZ4P), is **SZ < DZ < DZP < TZP < TZ2P < QZ4P**.

The choice of basis set is in general a trade off between accuracy and computation time: the more accurate the basis set, the more computationally demanding the calculation will be (both in term of CPU time and the memory usage).

As an example, in the following table we compare accuracy v.s. CPU time for a (24,24) carbon nanotube using different basis sets. "Energy error" is defined as the absolute error in the formation energy per atom using the QZ4P results as reference.[1]

Table 4.1: Accuracy and CPU time ratio for a (24,24) carbon nanotube using different basis sets

Basis Set	Energy Error [eV]	CPU time ratio (relative to SZ)
SZ	1.8	1
DZ	0.46	1.5
DZP	0.16	2.5
TZP	0.048	3.8
TZ2P	0.016	6.1
QZ4P	reference	14.3

It is worthwhile noting that the error in formation energies are to some extend systematic, and they partially cancel each other out when taking energy differences. For example, if one considers the difference in energy between two carbon nanotubes variants ((24,24) and (24-0)) with the same number of atoms, the basis set error is smaller than 1 milli-eV/atom already with a DZP basis set, which is much smaller than the absolute error in the individual energies. The same consideration holds for reactions barriers: the error in the energy difference between different conformations is much smaller than the error in the absolute energies themselves.

Band gaps:

The following figure shows the convergence WRT basis set of band gaps (XC:PBE). While DZ is often inaccurate (since DZ lacks any polarization function, the description of the virtual orbital space is very poor), TZP captures the trends very well.

In general, since the basis set might have different effects on different properties, it is advisable to run a few simple calculations to get an idea of the effect of the basis set with your property of interest.

---

[1] Computational details: Single Point calculation, 'Good' NumericalQuality, no frozen core, 7 k-points, XC functional: GGA:PBE. Calculation performed on a 24 cores compute node. 96 atoms in the unit cell.
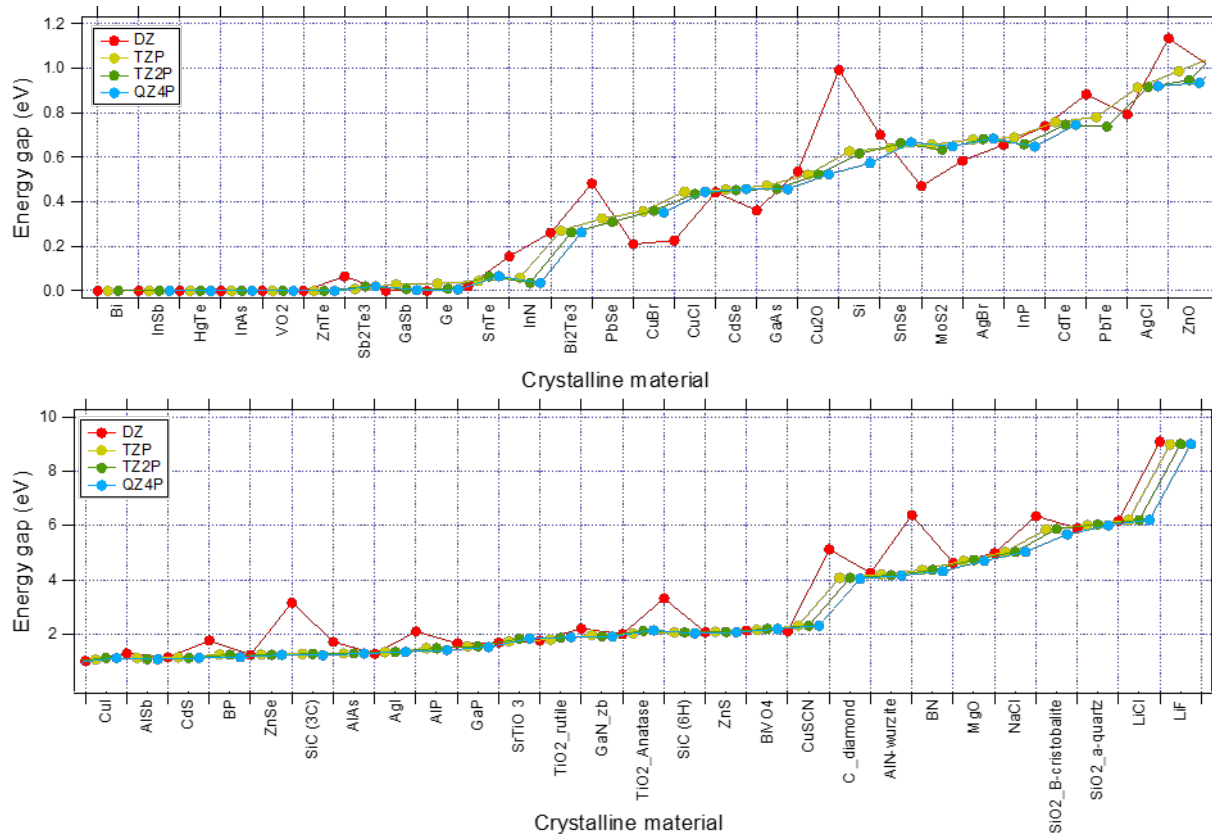

Fig. 4.1: Convergence of Band Gaps WRT basis set for various system. (XC:PBE, K-Space Quality: Good)

A summary of the basis sets:

- **SZ**: Single Zeta, the minimal basis set (only NAOs), serves mostly a technical purpose. The results are rather inaccurate, but it's computationally efficient. It can be useful for running a very quick test calculation. See also *SZ-SCF-Restart* (page 171).

- **DZ**: The Double Zeta basis set is computationally very efficient. It can be used for pre-optimization of structures (that should then be further optimized with a better basis set). Since it has no polarization functions, properties depending on the virtual orbital space will be rather inaccurate.

- **DZP**: Double zeta plus polarization function. Only available for main group elements up to Krypton. For other elements a TZP basis set will be used **automatically**. This is a reasonably good basis set for geometry optimizations of organic systems.

- **TZP**: The Triple Zeta plus Polarization basis set offers the best balance between performance and accuracy. This is the basis set we would generally recommend.

- **TZ2P**: The Triple Zeta plus Double Polarization basis set is an accurate basis set. It is qualitatively similar to TZP but quantitatively better. It should be used when a good description of the virtual orbital space is needed.

- **QZ4P**: Quadruple zeta plus Quadruple Polarization. This is the biggest basis set available. It can be used for benchmarking.

4.1.3 Frozen core

It is recommended to use the frozen core approximation, as it is faster, in particular for heavy elements.

In general, the frozen core approximation does not influence the results significantly (especially if one uses a `small` frozen core). For accurate results on certain properties (like *Properties at Nuclei* (page 108)) all electron basis sets are needed on the atoms of interest.

- For Meta-GGA XC functionals, it is recommended to use `small` or `none` frozen core (the frozen orbitals are computed using LDA and not the selected Meta-GGA)

- For optimizations under pressure, use `small` or `none` frozen core

Small, Medium, and Large frozen cores:

The possible choices for the `Basis%Core` keyword are `None`, `Small`, `Medium`, and `Large`. How does this map to the actual *Available Basis Sets* (page 50)? Obviously this depends on the element. As all elements have an all electron basis set defined, `None` maps always to this set. For the element H there are no frozen core sets available and all options can only lead to the all electron basis set. For elements like C there is a single frozen core available and the three choices (`Small`, `Medium`, `Large`) lead to the same choice: C.1s. Most elements have two frozen cores defined. In such a case the choices `Large` and `Medium` point to the larger one, and `Small` to the smallest one. With four choices `Large` maps to the largest one, `Medium` to the one below it, and `Small` to the smallest one. This table summarizes the logic

Table 4.2: Mapping of the `Basis%Core` keyword to available cores (if any)

#Available frozen cores	Example	None	Small	Medium	Large
0	H	H	H	H	H
1	C C.1s	C	C.1s	C.1s	C.1s
2	Na Na.1s Na.2p	Na	Na.1s	Na.2p	Na.2p
3	Rb Rb.3p Rb.3d Rb.4p	Rb	Rb.3p	Rb.3d	Rb.4p
4	Pb Pb.4d Pb.4f Pb.5p Pb.5d	Pb	Pb.4d	Pb.5p	Pb.5d

It is possible to control both the basis and core per atom type and per region, see *More Basis input options* (page 52).

4.1.4 Available Basis Sets

The basis set files, containing the definition of the basis set, are located in `$AMSHOME/atomicdata/Band`.

The next table gives an indication frozen core (*fc*) standard basis sets are available for the different elements in BAND. Note that all electron (*ae*) basis set are available for all basis sets types.

Table 4.3: Available standard basis sets for non-relativistic and ZORA calculations H-Ubn (Z=1-120)

Note: Not all combinations of basis set `Type` and `Core` are available for all elements. If a specific combination is not available, Band will pick the first *better* basis set. E.g. if an element is not in the DZP database, it is taken from the TZP basis set.

4.1.5 Pure STO and GTO basis sets

Starting from AMS2023, BAND includes many basis sets to reproduce literature data. The basis sets are suitable (and recommended) for well converged *GW* (page 110), *RPA* (page 22), and *double hybrid* (page 22) calculations in which electron-electron interaction effects are accounted for explicitly beyond DFT. Available basis sets are:

pure STO type basis sets

The TZ2P and QZ4P basis sets from ADF can now be used in BAND calculations as well. To get the same results as ADF, it is additionally necessary to disable the confinement of the basis functions *Confinement of basis functions* (page 54). Additionally, the CORR/TZ3P and the CORR/QZ6P basis sets of ADF can also be used with BAND. Band also includes the Corr/TZ3P_G and the Corr/QZ6P_GH basis sets which includes higher-angular momentum functions (g-functions fo TZ3P_G, g-,h- (and sometimes i-)functions for QZ6P_GH).

```
Basis Type=STO/TZ2PSTO
SoftConfinement Quality=Excellent # disable radial basis function confinement
```

Table 4.4: STO (all electron) basis sets for band

Basis Set	ADF
STO/TZ2PSTO	ZORA/TZ2P
STO/QZ4PSTO	ZORA/QZ4P
CORR/QZ6P	CORR/QZ6P
CORR/QZ6P_GH	
CORR/TZ3P	CORR/TZ3P
CORR/TZ3P_G	

Correlation consistent Gaussian type basis sets

See also:

Examples GTO (page 211)

BAND includes the correlation-consistent (CC) Dunning Gaussian type (GTO) basis sets from double Zeta (DZ) to hextuple Zeta (6Z) quality. GTO basis sets can only be used in non-relativistic calculations and can not be used with the frozen core approximation. The basis sets cc-pVDZ to cc-pV5Z are only available for the first four rows of the periodic table, with the exception of K (potassium) (see also: the information on the Basis Set Exchange (https://www.basissetexchange.org/). The cc-pV6Z basis set is only available for the elements of the first three rows of the periodic table with the exception of Li, Na, and Mg.

```
Basis Type=GTO/CC-PVTZ
SoftConfinement Quality=Excellent # disable radial basis function confinement
Relativity Level=None   # relativistic effects are currently not supported for GTOs
```

Table 4.5: GTO (all electron) basis sets for band

Basis Set	comment
GTO/CC-PV5Z	
GTO/CC-PV6Z	
GTO/CC-PVDZ	
GTO/CC-PVQZ	
GTO/CC-PVTZ	
GTO/CC-PWCVQZ	

GTO type basis sets can be used to calculate high-quality RPA and MP2/double-hybrid energies as well as GW QP

energies (MBPT based methods), often in combination with complete basis set (CBS) limit extrapolation of the form

$$E_{\text{CBS}} = \frac{Y^3 E_Y - X^3 E_X}{Y^3 - X^3}$$

where E_Y denotes an energy or QP energy calculated with the cc-pVYZ basis set and E_X denotes an energy or QP energy calculated with the cc-pVXZ basis set, and $Y > X$. Typically, an extrapolation from a cc-pVTZ and a cc-pVQZ calculation will give a result of cc-pV5Z quality at lower computational cost.

When used in conjunction with MBPT based methods, a highly accurate auxiliary fit set is needed (Also see the recommendations in the :ref: *MBPT section <MBPT>*). It is recommended to generate the auxiliary fit sets directly from products of basis functions to saturate all higher angular momentum channels. See the *RIHartreeFock documentation* (page 68).

4.1.6 More Basis input options

```
Basis
   Folder string
   PerAtomType
      Core [None | Small | Medium | Large]
      File string

      Type [SZ | DZ | DZP | TZP | TZ2P | QZ4P]
   End
   PerRegion
      Core [None | Small | Medium | Large]
      Region string
      Type [SZ | DZ | DZP | TZP | TZ2P | QZ4P]
   End
End
```

Basis

>> **Type** Block

>> **Description** Definition of the basis set

> **Folder**

>> **Type** String

>> **Description** Path to a folder containing the basis set files. This can be used for special use-defined basis sets. Cannot be used in combination with 'Type'

> **PerAtomType**

>> **Type** Block

>> **Recurring** True

>> **Description** Defines the basis set for all atoms of a particular type.

>> **Core**

>>> **Type** Multiple Choice

>>> **Options** [None, Small, Medium, Large]

>>> **Description** Size of the frozen core.

>> **File**

>>> **Type** String

Description The path to the basis set file. The path can be absolute or relative to $AMSRE-SOURCES/Band. Specifying the path to the basis file explicitly overrides the automatic basis file selection via the Type and Core subkeys.

Symbol

    Type String

    Description The symbol for which to define the basis set.

Type

    Type Multiple Choice

    Options [SZ, DZ, DZP, TZP, TZ2P, QZ4P]

    Description The basis sets to be used.

PerRegion

    Type Block

    Recurring True

    Description Defines the basis set for all atoms in a region. If specified, this overwrites the values set with the Basis%Type and Basis%PerAtomType keywords for atoms in that region. Note that if this keyword is used multiple times, the chosen regions may not overlap.

    Core

        Type Multiple Choice

        Default value Large

        Options [None, Small, Medium, Large]

        Description Size of the frozen core.

    Region

        Type String

        Description The identifier of the region for which to define the basis set. Note that this may also be a region expression, e.g. 'myregion+myotherregion' (the union of two regions).

    Type

        Type Multiple Choice

        Default value DZ

        Options [SZ, DZ, DZP, TZP, TZ2P, QZ4P]

        Description The basis sets to be used.

See also: *Example: Multiresolution* (page 202), and *Frozen core* (page 49).

4.1.7 Confinement of basis functions

It is possible to alter the radial part of the basis functions in order to make them more compact, which will in turn speeds up the calculation.

```
SoftConfinement
   Quality [Auto | Basic | Normal | Good | VeryGood | Excellent]
   Radius float
   Delta float
End
```

SoftConfinement

>**Type** Block

>**Description** In order to make the basis functions more compact, the radial part of the basis functions is multiplied by a Fermi-Dirac (FD) function (this 'confinement' is done for efficiency and numerical stability reasons). A FD function goes from one to zero, controlled by two parameters. It has a value 0.5 at Radius, and the decay width is Delta.

>**Quality**

>>**Type** Multiple Choice

>>**Default value** Auto

>>**Options** [Auto, Basic, Normal, Good, VeryGood, Excellent]

>>**GUI name** Confinement

>>**Description** In order to make the basis functions more compact, the radial part of the basis functions is multiplied by a Fermi-Dirac (FD) function (this 'confinement' is done for efficiency and numerical stability reasons). A FD function goes from one to zero, controlled by two parameters. It has a value 0.5 at Radius, and the decay width is Delta.

>>This key sets the two parameters 'Radius' and 'Delta'.

>>Basic: Radius=7.0, Delta=0.7; Normal: Radius=10.0, Delta=1.0; Good: Radius=20.0, Delta=2.0; VeryGood and Excellent: no confinement at all.

>>If 'Auto', the quality defined in the 'NumericalQuality' will be used.

>**Radius**

>>**Unit** Bohr

>>**Description** Explicitly specify the radius parameter of the Fermi-Dirac function.

>**Delta**

>>**Type** Float

>>**Unit** Bohr

>>**Description** Explicitly specify the delta parameter of the Fermi-Dirac function (if not specified, it will be 0.1*Radius).

- For geometry optimizations under pressure, `Basic` soft confinement is recommended.

4.1.8 Manually specifying AtomTypes (expert option)

AtomType (block-type) (*Expert Option*) Description of the atom type. Contains the block keys `Dirac`, `BasisFunctions` and `FitFunctions`. The key corresponds to one atom type. The ordering of the `AtomType` keys (in case of more than one atom type) is **NOT** arbitrary. It is interpreted as corresponding to the ordering of the `Atoms` keys. The n-th `AtomType` key supplies information for the numerical atom of the nth type, which in turn has atoms at positions defined by the nth `Atoms` key.

```
AtomType ElementSymbol
   Dirac ChemSym
      {option}
      ...
      shells cores
      shell_specification {occupation_number}
      ...
   End
   {BasisFunctions
      shell_specification STO_exponent
      ...
   End}
   FitFunctions
      shell_specification STO_exponent
      ...
   End
END
```

The argument *ElementSymbol* to `AtomType` is the symbol of the element that is referred to in the `Atoms` key block.

Dirac (block-type) Specification of the numerical ('Herman-Skillman') free atom, which defines the initial guess for the SCF density, and which also (optionally) supplies Numerical Atomic Orbitals (NOs) as basis functions, and/or as STO fit functions for the crystal calculation. The argument *ChemSym* of this option is the symbol of the element of the atom type. The data records of the `Dirac` key are:

1. the number of atomic shells (1s,2s,2p,etc.) and the nr. of core-shells (two integers on one line).

2. specification of the shell and its electronic occupation.

This specification can be done via quantum numbers or using the standard designation (e.g. '1 0' is equivalent to '1s'). Optionally one may insert anywhere in the Dirac block a record *Valence*, which signifies that all numerical valence orbitals will be used as basis functions (NOs) in the crystal calculation. You can also insert *NumericalFit* followed by a number (max. l-value) in the key block, which causes the program to use numerical STO fit functions. For example NumericalFit 2 means that the squares of all s,p, and d NOs will be used as STO fit functions with $l = 0$, since the NOs are spherically symmetric. If you insert *Spinor*, a spin-orbit relativistic calculation for the single-atom will be carried out.

The Herman-Skillman program generates all its functions (atomic potential, charge density, one-electron states) as tables of values in a logarithmic radial grid. The number of points in the grid, and the min. and max. r-value are defaulted at 3000, 0.000001, and 100.0 (a.u.) respectively. These defaults can be overwritten by specifying anywhere in the Dirac block the (sub)keys *radial*, *rmin* and *rmax*.

The program will do a spin-unrestricted calculation for the atoms in addition to the restricted one. The occupation of the spin-orbitals will be of maximum spin-multiplicity and cannot be controlled in the Dirac key-block.

BasisFunctions (block-type) Slater-type orbitals, specified by quantum numbers n,:math:l or by the letter designation (e.g. 2p) and one real (alpha) per STO. One STO per record. Use of this key is optional in the sense that Slater-type functions are not needed if other basis functions have been specified (i.e. the numerical atomic orbitals, see key Dirac).

FitFunctions (block-type) Slater-type fit functions, described in the same way as in `BasisFunc-tions`. Each `FitFunctions` key corresponds to one atom type, the type being the one of the preceding `Dirac` key. The selection choice of a 'good' fit set is a matter of experience. Fair quality sets are included in the database of the molecular program ADF.

Example:

```
AtomType C :: Carbon atom
   Dirac C
      3 1
   VALENCE
      1s
      2s
      2p 2.0
   End
   BasisFunctions
      1s 1.7
      ...
   End
   FitFunctions
      1s 13.5
      2s 11.0
      ...
   End
End
```

TestFunctions (block-type) An optional subkey of the `AtomType` key block is `TestFunctions` which has the same format as the `BasisFunctions` and `FitFunctions` blocks. The `TestFunctions` block specifies STOs to be used as test functions in the numerical integration package. For the time being the l value is ignored. A possible application is to include a very tight function, to increase the accuracy near a nucleus.

4.1.9 Basis Set Superposition Error (BSSE)

The Ghost Atom feature enables the calculation of Basis Set Superposition Errors (BSSE). Normally, if you want to know the bonding energy of system A with system B you calculate three energies

1) $E(A + B)$

2) $E(A)$

3) $E(B)$

The bond energy is then $E(A + B) - E(A) - E(B)$

The BSSE correction is about the idea that we can also calculate E(A) including basis functions from molecule B.

You can make a ghost atom by simply adding "Gh." in front of the element name, for instance "Gh.H" for a ghost hydrogen , "Gh.C" for a ghost Carbon atom.

You will get a better bonding energy, closer to the basis set limit by calculating

$E(A + B) - E(\text{A with B as ghost}) - E(\text{B with A as ghost})$

The BSSE correction is

$E(A) - E(\text{A with B as ghost}) + E(B) - E(\text{B with A as ghost})$

See also:

Example: BSSE correction (page 204)

4.1.10 Alternative elements / Virtual crystal approximation

It is possible to define an alternative nuclear charge for an element. If a certain site in a crystal has, say, a 50% occupation of C (Z=6) and a 50% occupation of B (Z=5) you can use one alternative atom with Z=5.5

Example:

```
Atoms
   Si 0.0 0.0 0.0
   C  0.0 0.0 0.0 nuclear_charge=5.5   ! this site has a mixture of 50% C and B
End
```

In this example the basis set is taken from the C atom, but you could equally well specify the B atom here. (In fact any atom type can be specified here, but why would you like to use an Au basis set for this situation.). Defining such an average element is in the spirit of the Virtual Crystal Approximation (VCA), however, the fractional nuclear charge approach does not work well when for instance the fractional z is near the value of a noble gas. For instance when mixing Si (Z=14) and C(Z=8) atoms you may get near Ne (Z=10), and the corresponding lattice will be way too diffuse.

If you want to perform a scan it can be useful to use the ModifyAlternativeElement option

Example:

```
System
   ModifyAlternativeElements true

   Atoms
      Si 0.0 0.0 0.0
      H  0.0 0.0 0.0 nuclear_charge=5.6   ! Element H is ignored and will be "rounded
↪" to nearest atom (for the basis set) in this case C
   End
```

In band an alternative element works well with the frozen core approximation, using a smaller or no core has little effect. The VCA relies on defining an average pseudopotential (commonly used in plane wave programs) and is not identical to the alternative element approach (defining an average nuclear charge).

4.2 K-Space

The K-Space sampling (i.e., the k-points used to sample the Brillouin Zone) is an important technical aspect of Band, as it influences heavily the accuracy, the CPU time and the memory usage of the calculation (see section *Recommendations for k-space* (page 60)).

4.2.1 KSpace input block

The K-Space can be controlled via the `KSpace` input block. Two different k-space integration methods are available: the *Regular Grid* (**default**) and the *Symmetric Grid*.

```
KSpace
   Type [Regular | Symmetric]
   Quality [Auto | GammaOnly | Basic | Normal | Good | VeryGood | Excellent]
End
```

KSpace

> **Type** Block
>
> **Description** Options for the k-space integration (i.e. the grid used to sample the Brillouin zone)

Type

> **Type** Multiple Choice
>
> **Default value** Regular
>
> **Options** [Regular, Symmetric]
>
> **GUI name** K-space grid type
>
> **Description** The type of k-space integration grid used to sample the Brillouin zone (BZ) used.
>
> > 'Regular': simple regular grid.
> >
> > 'Symmetric': symmetric grid for the irreducible wedge of the first BZ (useful when high-symmetry points in the BZ are needed to capture the correct physics of the system, graphene being a notable example).

Quality

> **Type** Multiple Choice
>
> **Default value** Auto
>
> **Options** [Auto, GammaOnly, Basic, Normal, Good, VeryGood, Excellent]
>
> **GUI name** K-space
>
> **Description** Select the quality of the K-space grid used to sample the Brillouin Zone. If 'Auto', the quality defined in the 'NumericalQuality' will be used. If 'GammaOnly', only one point (the gamma point) will be used.
>
> > The actual number of K points generated depends on this option and on the size of the unit cell. The larger the real space cell, the fewer K points will be generated.
> >
> > The CPU-time and accuracy strongly depend on this option.

Regular K-Space grid

By default, Band will look at the size of a lattice vectors and the KSpace quality to determine the number of k-points. The larger the lattice vector in real space, the smaller the reciprocal space vectors are, and as a result fewer k-points are needed. The following intervals will be distinguished: 0-5 Bohr, 5-10 Bohr, 10-20 Bohr, 20-50 Bohr, and beyond. Here is the table explaining how many k-points will be used along a lattice vector.

Lattice vector length	Basic	Normal	Good	VeryGood	Excellent
0-5 Bohr	5	9	13	17	21
5-10 Bohr	3	5	9	13	17
10-20 Bohr	1	3	5	9	13
20-50 Bohr	1	1	3	5	9
50- Bohr…	1	1	1	3	5

By preferring odd-numbered values we can use a quadratic interpolation method, and have the Γ point in the grid. It is then reasonable to assume a decaying error when going to a better quality setting.

It is also possible to manually specify the number of k-space points along each reciprocal lattice vector

```
KSpace
   Regular
      NumberOfPoints integer_list
   End
End
```

KSpace

>> **Type** Block
>>
>> **Description** Options for the k-space integration (i.e. the grid used to sample the Brillouin zone)

> **Regular**

>> **Type** Block
>>
>> **Description** Options for the regular k-space integration grid.

> **NumberOfPoints**

>> **Type** Integer List
>>
>> **Description** Use a regular grid with the specified number of k-points along each reciprocal lattice vector.
>>
>> For 1D periodic systems you should specify only one number, for 2D systems two numbers, and for 3D systems three numbers.

Symmetric K-Space grid (tetrahedron method)

The tetrahedron method can be useful when high symmetry points in the BZ are needed to capture the correct physics of the system, graphene being a notable example.

The number of k-points in the symmetric grid depends on the KSpace quality and on the length of the shortest lattice vector.

It is also possible to manually specify the symmetric k-space integration parameter:

```
KSpace
   Symmetric
      KInteg integer
   End
End
```

KSpace

>> **Type** Block
>>
>> **Description** Options for the k-space integration (i.e. the grid used to sample the Brillouin zone)

> **Symmetric**

>> **Type** Block
>>
>> **Description** Options for the symmetric k-space integration grid.

> **KInteg**

>> **Type** Integer
>>
>> **GUI name** Accuracy
>>
>> **Description** Specify the accuracy for the Symmetric method.
>>
>> 1: absolutely minimal (only the G-point is used) 2: linear tetrahedron method, coarsest spacing 3: quadratic tetrahedron method, coarsest spacing 4,6,… (even): linear tetrahedron method 5,7…. (odd): quadratic method
>>
>> The tetrahedron method is usually by far inferior.

General Remark: The tetrahedron method samples the irreducible wedge of the first BZ, whereas the regular grid samples the whole, first BZ. As a rule of thumb you need to choose roughly twice the value for the regular grid. For example kspace 2 compares to grid 4 4 4, kspace 3 to grid 5 5 5, etc.. Sticking to this rule the number of unique k-points will be roughly similar.

4.2.2 Recommendations for k-space

Which K-Space quality to use depends very much a) the system you are studying and b) the property you are interested in. We strongly recommend you to test the effect of different K-Space qualities on your system and properties of interest.

As an example, in the following table we list the errors on formation energy and band gap for diamond using regular k-space grids of different qualities (using Excellent kSpace quality as reference).

Table 4.6: Accuracy of formation energy for diamond (primitive unit cell) using different KSpace grids

KSpace quality	Energy error / atom [eV]	CPU time ratio
Gamma-Only	3.3	1
Basic	0.6	2
Normal	0.03	6
Good	0.002	16
VeryGood	0.0001	35
Excellent	reference	64

It is worthwhile noting that the errors due to finite k-space sampling in formation energies are to some extend systematic, and they partially cancel each other out when taking energy differences.

In general, metals (or narrow-gap semiconductor) require higher K-Space sampling than insulators. For insulators and wide-gap semiconductors, Normal K-Space quality often suffices. For Narrow-gap semiconductor and metals, Good K-Space quality is highly recommended. For geometry optimizations under pressure, Good K-Space quality is recommended.

Furthermore for certain properties, such as band gaps, Normal K-Space quality might not be enough to obtain reliable results. For example, in following figure we see how Normal K-Space quality is often not enough for computing band gaps (especially for the narrow-gap semiconductor of the top panel). For band gap prediction, it is recommended to use Good K-Space quality.

High symmetry points and the regular grid

Using the symmetric k-grid it is ensured that points with high symmetry are included. However, for the default regular grid this is not the case. An important example is graphene. Its band structure has a conical intersection at the point labeled "K", in all other k-points there is a gap.

Table 4.7: The magical values for which the regular k-grid includes the high symmetry point "K" (with fractional coordinates 1/3,1/3) for a honeycomb lattice.

grid	point "K" included?	K-grid quality for Graphene
5x5	No	Normal
7x7	Yes	
9x9	No	Good
11x11	No	
13x13	Yes	VeryGood
15x15	No	
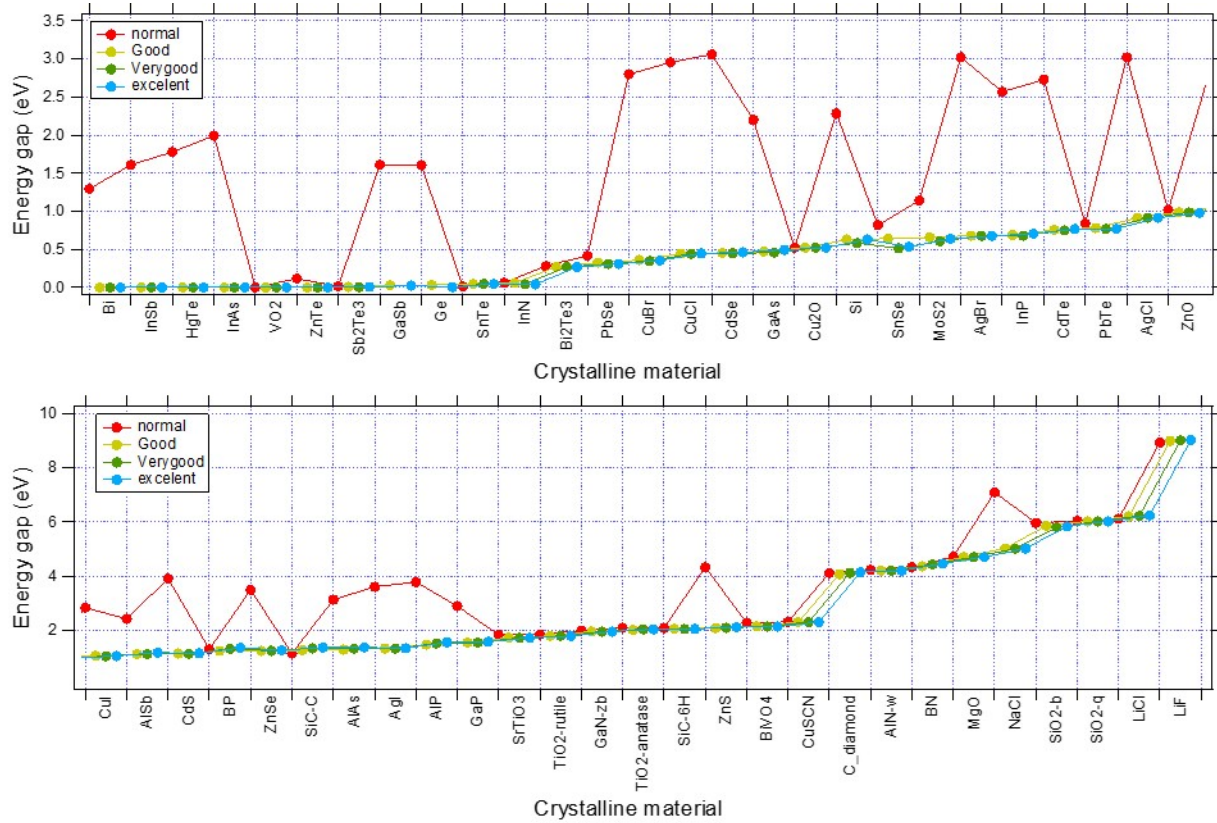

Fig. 4.2: Convergence of band gaps WRT the k-space quality set for various system. (XC:PBE, Basis:TZP)

But in general it makes more sense to use the symmetric k-grid if points of high symmetry are deemed important.

4.3 Numerical Integration

Many of the integrals needed by Band are computed via numerical integration. See also: Wikipedia page on Numerical Integration (https://en.wikipedia.org/wiki/Numerical_integration).

4.3.1 Becke Grid

The numerical integration grid is a refined version of the fuzzy cells integration scheme developed by Becke[1]. The implementation in BAND is described in Ref.[2].

The quality of the Becke integration grid can be changed within the `BeckeGrid` block:

```
BeckeGrid
   Quality [Auto | Basic | Normal | Good | VeryGood | Excellent]
   RadialGridBoost float
   QualityPerRegion
      Quality [Basic | Normal | Good | VeryGood | Excellent]
      Region string
   End
End
```

BeckeGrid

> **Type** Block
>
> **Description** Options for the numerical integration grid, which is a refined version of the fuzzy cells integration scheme developed by Becke.

Quality

> **Type** Multiple Choice
>
> **Default value** Auto
>
> **Options** [Auto, Basic, Normal, Good, VeryGood, Excellent]
>
> **Description** Quality of the integration grid. For a description of the various qualities and the associated numerical accuracy see reference. If 'Auto', the quality defined in the 'NumericalQuality' will be used.

RadialGridBoost

> **Type** Float
>
> **Default value** 1.0
>
> **Description** The number of radial grid points will be boosted by this factor. Some XC functionals require very accurate radial integration grids, so BAND will automatically boost the radial grid by a factor 3 for the following numerically sensitive functionals: LibXC M05, LibXC M05-2X, LibXC M06-2X, LibXC M06-HF, LibXC M06-L, LibXC M08-HX, LibXC M08-SO, LibXC M11-L, LibXC MS0, LibXC MS1, LibXC MS2, LibXC MS2H, LibXC MVS, LibXC MVSH, LibXC N12, LibXC N12-SX, LibXC SOGGA11, LibXC SOGGA11-X, LibXC TH1, LibXC

QualityPerRegion

>> **Type** Block

>> **Recurring** True

>> **Description** Sets the grid quality for all atoms in a region. If specified, this overwrites the globally set quality.

>> **Quality**

>>> **Type** Multiple Choice

>>> **Options** [Basic, Normal, Good, VeryGood, Excellent]

>>> **Description** The region's integration grid quality.

>> **Region**

>>> **Type** String

>>> **Description** The identifier of the region for which to set the quality.

Example: Multiresolution (page 202) illustrates how to use the `QualityPerRegion` option.

Notes:

- The space-partition function used in BAND differs from the one described in Ref.[?]. The unnormalized partition function used in the program is defined as (Ω_I is an element-dependent parameter: 0.1 Bohr for H, 0.3 Bohr for He-Xe and 0.6 Bohr for Cs-Ubn):

$$\mathcal{P}_{i,U} = \begin{cases} 1 & \text{if } r_{i,U} < \Omega_I \\ 0 & \text{if } \exists j : r_{j,U} < \Omega_J \\ \eta_i \frac{e^{-2(r_{i,U}-\Omega_I)/a_0}}{(r_{i,U}-\Omega_I)^2} & \text{elsewhere} \end{cases}$$

- The Becke grid is not very well suited to calculate Voronoi deformation density (VDD) charges. For accurate calculation of VDD charges the Voronoi integration scheme is recommended.

4.3.2 Radial grid of NAOs

```
RadialDefaults

> **NR**

>> **Type** Integer

>> **Default value** 3000

Description Number of radial points. With very high values (like 30000) the Dirac subprogram may not converge.

NRPerType

   Type Integer List

   Description If present overrides NR. The list needs to be as long as there are atom types

RMax

   Type Float

   Default value 100.0

   Unit Bohr

   Description Upper bound of the logarithmic radial grid

RMin

   Type Float

   Default value 1e-06

   Unit Bohr

   Description Lower bound of the logarithmic radial grid

RMinPerType

   Type Float List

   Unit Bohr

   Description If specified overrides RMin. The list needs to be as long as there are atom types (different elements)

4.3.3 Voronoi grid (deprecated)

It is possible to use an alternative numerical integration scheme to the Becke Grid, namely the Voronoi Grid.

```
IntegrationMethod [Becke | Voronoi]
```

IntegrationMethod

   Type Multiple Choice

   Default value Becke

   Options [Becke, Voronoi]

   Description Choose the real-space numerical integration method. Note: the Voronoi integration scheme is deprecated.

The options for the Voronoi Grid are specified in the `Integration` block:

```
Integration
   AccInt float
End
```

Integration

   Type Block

Description Options for the Voronoi numerical integration scheme. Deprecated. Use BeckeGrid instead.

AccInt

> **Type** Float
>
> **Default value** 3.5
>
> **Description** General parameter controlling the accuracy of the Voronoi integration grid. A value of 3 would be basic quality and a value of 7 would be good quality.

4.4 Density Fitting

The Coulomb potential in Band is computed using a method called density fitting. The density fitting scheme in BAND is called **Zlm Fit**, and it is described in reference[1]. The ZlmFit is also used to compute (when needed) the gradient and hessian of the electron density.

4.4.1 Zlm Fit

The idea behind Zlm Fit can be summarized as follows: the total electron density is split into localized atomic densities (in a similar way as the volume is partitioned in the Becke grid). These atomic densities are then approximated by a combination of radial spline functions and real spherical harmonics (Zlm), for which the Coulomb potential can be easily computed.

```
ZlmFit
   Quality [Auto | Basic | Normal | Good | VeryGood | Excellent]
   QualityPerRegion
      Quality [Basic | Normal | Good | VeryGood | Excellent]
      Region string
   End
End
```

ZlmFit

> **Type** Block
>
> **Description** Options for the density fitting scheme 'ZlmFit'.

Quality

> **Type** Multiple Choice
>
> **Default value** Auto
>
> **Options** [Auto, Basic, Normal, Good, VeryGood, Excellent]
>
> **GUI name** Spline Zlm fit
>
> **Description** Quality of the density-fitting approximation. For a description of the various qualities and the associated numerical accuracy see reference. If 'Auto', the quality defined in the 'NumericalQuality' will be used.

QualityPerRegion

> **Type** Block

---

[1] M. Franchini, P.H.T. Philipsen, E. van Lenthe, L. Visscher, *Accurate Coulomb Potentials for Periodic and Molecular Systems through Density Fitting*, Journal of Chemical Theory and Computation 10, 1994 (2014) (https://doi.org/10.1021/ct500172n).

Recurring True

Description Sets the ZlmFit quality for all atoms in a region. If specified, this overwrites the globally set quality.

Quality

> **Type** Multiple Choice
>
> **Options** [Basic, Normal, Good, VeryGood, Excellent]
>
> **Description** The region's quality of the ZlmFit.

Region

> **Type** String
>
> **Description** The identifier of the region for which to set the quality.

Example: Multiresolution (page 202) illustrates how to use the `QualityPerRegion` option.

Expert options

```
ZlmFit
   LMargin integer
   AllowBoost Yes/No
   DensityThreshold float
   PartitionFunThreshold float
   FGaussianW float
   FGridSpacing float
   FKSpaceCutOff float
   FirstTopoCell integer
   LastTopoCell integer
   OrderTopoTrick integer
   NumStarsPartitionFun integer
End
```

ZlmFit

> **Type** Block
>
> **Description** Options for the density fitting scheme 'ZlmFit'.

LMargin

> **Type** Integer
>
> **Description** User-defined l-margin, i.e., l_max for fitting is max(lMargin + l_max_basis_function, 2*l_max_basis_function). Depends on Quality and normally is 4

AllowBoost

> **Type** Bool
>
> **Default value** Yes
>
> **Description** Allow automatic atom-dependent tuning of maximum l of spherical harmonics expansion. Whether or not this boost is needed for a given atom is based on an heuristic estimate of how complex the density around that atom is.

DensityThreshold

> **Type** Float

> **Description** Threshold below which the electron density is considered to be negligible. Depends on Quality and is normally 1.0e-7

PartitionFunThreshold

> **Type** Float
>
> **Default value** 0.0
>
> **Description** Threshold for the partition functions: if an integration point has a partition function weight smaller than this threshold, it will be discarded.

FGaussianW

> **Type** Float
>
> **Default value** 1.0
>
> **Description** Only for 3D periodic systems. Width of the Gaussian functions replacing the S and P Zlms for Fourier transform.

FGridSpacing

> **Type** Float
>
> **Description** Only for 3D periodic systems. Spacing for the Fourier grid. By default, this depends on the quality.

FKSpaceCutOff

> **Type** Float
>
> **Description** Only for 3D periodic systems. Cut-off of the grid in k-space for the Fourier transform.

FirstTopoCell

> **Type** Integer
>
> **Default value** 5
>
> **Description** First cell for the topological extrapolation of the long range part of the Coulomb Potential.

LastTopoCell

> **Type** Integer
>
> **Default value** 10
>
> **Description** Last cell for the topological extrapolation of the long range part of the Coulomb Potential.

OrderTopoTrick

> **Type** Integer
>
> **Default value** 3
>
> **Description** Order of the topological extrapolation of the long range part of the Coulomb Potential.

NumStarsPartitionFun

> **Type** Integer
>
> **Default value** 5
>
> **Description** Number of cell stars to consider when computing the partition function.

4.4.2 STO Fit (Deprecated)

In previous version of BAND (pre2014) this was the default option, which is now replaced by Zlm Fit. It is still used in the context of `NMR` and `OldResponse` calculations.

4.5 Hartree–Fock RI

The Hartree-Fock exchange matrix is calculated through a procedure known as Resolution of the Identity (RI). The implementation of the RI scheme in BAND is loosely based on work by Ren *et al.*[1] For more information on hybrid functionals in BAND, see the *XC section* (page 13).

Technical aspects of the RI scheme can be tweaked in the `RIHartreeFock` block:

```
RIHartreeFock
   Quality [Auto | VeryBasic | Basic | Normal | Good | VeryGood | Excellent]
   FitSetQuality [Auto | VeryBasic | Basic | Normal | Good | VeryGood | Excellent |␣
→FromBasisProducts]
   DependencyThreshold float
   QualityPerRegion
      Quality [VeryBasic | Basic | Normal | Good | VeryGood | Excellent]
      Region string
   End
End
```

RIHartreeFock

> **Type** Block
>
> **Description**

Quality

> **Type** Multiple Choice
>
> **Default value** Auto
>
> **Options** [Auto, VeryBasic, Basic, Normal, Good, VeryGood, Excellent]
>
> **Description** Numerical accuracy of the RI procedure. If 'Auto', the quality specified in the 'NumericalQuality' will be used.

FitSetQuality

> **Type** Multiple Choice
>
> **Default value** Auto
>
> **Options** [Auto, VeryBasic, Basic, Normal, Good, VeryGood, Excellent, FromBasisProducts]
>
> **Description** The quality of auxiliary fit set employed in the RI scheme.
>
> > If 'Auto', the value of the RIHartreeFock Quality option will be used.
> >
> > Normal quality is generally sufficient for basis sets up to and including TZ2P.
> >
> > For larger basis sets (or for benchmarking purposes) a VeryGood fit set is recommended.
> >
> > Note that the FitSetQuality heavily influences the computational cost of the calculation.

---

[1] X. Ren, P. Rinke, V. Blum, J. Wieferink, A. Tkatchenko, A. Sanfilippo, K. Reuter and M. Scheffler, *Resolution-of-identity approach to Hartree–Fock, hybrid density functionals, RPA, MP2 and GW with numeric atom-centered orbital basis functions*, New J. Phys. 14 053020 (https://doi.org/10.1088/1367-2630/14/5/053020).

DependencyThreshold

> **Type** Float
>
> **Default value** 0.001
>
> **Description** To improve numerical stability, almost linearly-dependent combination of basis functions are removed from the Hartree-Fock exchange matrix.
>
> > If you obtain unphysically large bond energy in an Hybrid calculation, or an unphysically low correlation energy in an RPA, MP2, or double hybrid calculation, you might try setting the DependencyThreshold to a larger value (e.g. 3.0E-3)
> >
> > Note, that in GW calculations and GW-BSE calculations the default for this key is 5.0e-3.

QualityPerRegion

> **Type** Block
>
> **Recurring** True
>
> **Description** Sets the fit-set quality for all atoms in a region. If specified, this overwrites the globally set quality.

> **Quality**
>
> > **Type** Multiple Choice
> >
> > **Options** [VeryBasic, Basic, Normal, Good, VeryGood, Excellent]
> >
> > **Description** This region's quality of the auxiliary fit set employed in the RI scheme.

> **Region**
>
> > **Type** String
> >
> > **Description** The identifier of the region for which to set the quality.

For efficiency and numerical stability reasons, it is advisable to include:

```
SoftConfinement
  Quality Basic
End
```

See the *Confinement of basis functions* (page 54) section for more info.

Notes: for periodic systems it is only possible to use short-range hybrid functionals (*e.g.* HSE06) and all-electron basis sets.

Note:

- In AMS2019.3 the fit set for `FitSetQuality Good` has been improved.

4.6 Self Consistent Field (SCF)

The SCF procedure searches for a self-consistent density. The self-consistent error is the square root of the integral of the squared difference between the input and output density of the cycle operator.

$$\text{err} = \sqrt{\int dx \ (\rho_{\text{out}}(x) - \rho_{\text{in}}(x))^2}$$

When the SCF error is below a certain criterion, controlled by subkey `Criterion` of block key `Convergence`, convergence is reached. The default criterion depends on the `NumericalQuality` key.

Table 4.8: The default `Convergence%Criterion` depends on the `NumericalQuality` and on the number of atoms in the unit cell.

NumericalQuality	Convergence%Criterion
Basic	1e-5 $\sqrt{N_{\text{atoms}}}$
Normal	1e-6 $\sqrt{N_{\text{atoms}}}$
Good	1e-7 $\sqrt{N_{\text{atoms}}}$
VeryGood	1e-8 $\sqrt{N_{\text{atoms}}}$

The default method is the so-called MultiStepper. The MultiStepper is flexible, but somewhat harder to control by the user.

See also:

Troubleshooting: *SCF does not converge* (page 171)

4.6.1 SCF block

```
SCF
   Eigenstates Yes/No
   Iterations integer
   Method [DIIS | MultiSecant | MultiStepper]
   Mixing float
   MultiStepperPresetPath string
   PMatrix Yes/No
   PrintAllOccupiedBands Yes/No
   PrintAllVirtualBands Yes/No
   PrintAlwaysBandRanges Yes/No
   Rate float
   VSplit float
End
```

SCF

> **Type** Block
>
> **Description** Controls technical SCF parameters.

Eigenstates

> **Type** Bool
>
> **Description** The program knows two alternative ways to evaluate the charge density iteratively in the SCF procedure: from the P-matrix, and directly from the squared occupied eigenstates. By default the program actually uses both at least one time and tries to take the most efficient. If present, Eigenstates turns off this comparison and lets the program stick to one method (from the eigenstates).

Iterations

>   **Type** Integer
>
>   **Default value** 300
>
>   **GUI name** Maximum number of cycles
>
>   **Description** The maximum number of SCF iterations to be performed.

Method

>   **Type** Multiple Choice
>
>   **Default value** MultiStepper
>
>   **Options** [DIIS, MultiSecant, MultiStepper]
>
>   **Description** Choose the general scheme used to converge the density in the SCF. In case of scf problems one can try the MultiSecant alternative at no extra cost per SCF cycle. For more details see the DIIS and MultiSecantConfig block.

Mixing

>   **Type** Float
>
>   **Default value** 0.075
>
>   **Description** Initial 'damping' parameter in the SCF procedure, for the iterative update of the potential: new potential = old potential + mix (computed potential-old potential). Note: the program automatically adapts Mixing during the SCF iterations, in an attempt to find the optimal mixing value.

MultiStepperPresetPath

>   **Type** String
>
>   **Default value** DFTB/default2023.inc
>
>   **Description** Name of file containing a SCFMultiStepper key block. This will be used if no Explicit SCFMultiStepper block is in the input, and Method=MultiStepper. If the path is not absolute, it is relative to $AMSHOME/data/presets/multi_stepper'

PMatrix

>   **Type** Bool
>
>   **Description** If present, evaluate the charge density from the P-matrix. See also the key Eigenstates.

PrintAllOccupiedBands

>   **Type** Bool
>
>   **Default value** Yes
>
>   **Description** When printing the ranges of the bands, include all occupied ones.

PrintAllVirtualBands

>   **Type** Bool
>
>   **Default value** No
>
>   **Description** When printing the ranges of the bands, include all virtual ones.

PrintAlwaysBandRanges

>   **Type** Bool

Default value No

Description Normally the ranges of the bands are only printed at the last SCF cycle

Rate

Type Float

Default value 0.99

Description Minimum rate of convergence for the SCF procedure. If progress is too slow the program will take measures (such as smearing out occupations around the Fermi level, see key Degenerate of block Convergence) or, if everything seems to fail, it will stop

VSplit

Type Float

Default value 0.05

Description To disturb degeneracy of alpha and beta spin MOs the value of this key is added to the beta spin potential at the startup.

4.6.2 Convergence

All options and parameters related to the convergence behavior of the SCF procedure are defined in the `Convergence` block key. Also the finite temperature distribution is part of this

```
Convergence
   Criterion float
   CriterionFactor float
   Degenerate string
   ElectronicTemperature float
   InitialDensity [rho | psi | frompot]
   LessDegenerate Yes/No
   ModestCriterion float
   NoDegenerate Yes/No
   NumBoltz integer
   SpinFlip integer_list
   SpinFlipEnabled Yes/No
   SpinFlipRegion string
   StartWithMaxSpin Yes/No
   StartWithMaxSpinForSO Yes/No
End
```

Convergence

Type Block

Description Options and parameters related to the convergence behavior of the SCF procedure.

Criterion

Type Float

Description Criterion for termination of the SCF procedure. The default depends on the NumericalQuality and on the number of atoms in the system. Can be used for EngineAutomations

CriterionFactor

Type Float

Default value 1.0

Description Multiply Criterion (which depends on system and quality) with this factor. Can be used for EngineAutomations

Degenerate

    Type String

    Default value default

    Description Smooths (slightly) occupation numbers around the Fermi level, so as to insure that nearly-degenerate states get (nearly-) identical occupations. Be aware: In case of problematic SCF convergence the program will turn this key on automatically, unless the key 'Nodegenerate' is set in input. The smoothing depends on the argument to this key, which can be considered a 'degeneration width'. When the argument reads default, the program will use the value 1e-4 a.u. for the energy width.

ElectronicTemperature

    Type Float

    Default value 0.0

    Unit Hartree

    Description (KT) Specify this key for a gradient independent electronic temperature

InitialDensity

    Type Multiple Choice

    Default value rho

    Options [rho, psi, frompot]

    Description The SCF is started with a guess of the density. There are the following choices RHO: the sum of atomic density. PSI: construct an initial eigensystem by occupying the atomic orbitals. The guessed eigensystem is orthonormalized, and from this the density is calculated/

LessDegenerate

    Type Bool

    Default value No

    Description If smoothing of occupations over nearly degenerate orbitals is applied (see Degenerate key), then, if this key is set in the input file, the program will limit the smoothing energy range to 1e-4 a.u. as soon as the SCF has converged 'halfway', i.e. when the SCF error has decreased to the square root of its convergence criterion.

ModestCriterion

    Type Float

    Default value -1.0

    Description If this is specified band will consider the SCF converged if the error is below this criterion (after using the maximum number of iterations).

NoDegenerate

    Type Bool

    Default value No

    Description This key prevents any internal automatic setting of the key DEGENERATE.

NumBoltz

Type Integer

Default value 10

Description The electronic temperature is done with a Riemann Stieltjes numerical integration, between zero and one occupation. This defines the number of points to be used.

SpinFlip

Type Integer List

GUI name Flip spin for atoms

Description List here the atoms for which you want the initial spin polarization to be flipped. This way you can distinguish between ferromagnetic and anti ferromagnetic states. Currently, it is not allowed to give symmetry equivalent atoms a different spin orientation. To achieve that you have to break the symmetry.

SpinFlipEnabled

Type Bool

Default value Yes

Description If set to False, the keys SpinFlip and SpinFlipRegion are ignored. Only useful/convenient when trying to compare in a script the effect of spin flip.

SpinFlipRegion

Type String

Recurring True

GUI name Flip spin for region

Description Specify here the region for which you want the initial spin polarization to be flipped. This way you can distinguish between ferromagnetic and anti ferromagnetic states. Currently, it is not allowed to give symmetry equivalent atoms a different spin orientation. To achieve that you have to break the symmetry.

StartWithMaxSpin

Type Bool

Default value Yes

Description To break the initial perfect symmetry of up and down densities there are two strategies. One is to occupy the numerical orbitals in a maximum spin configuration. The alternative is to add a constant to the potential. See also Vsplit key.

StartWithMaxSpinForSO

Type Bool

Default value No

Description Same as the StartWithMaxSpin option. In case of spin-orbit band always used to split the potential. Now will use maxspin in case of SpinFlip. With this option it will always do that.

4.6.3 DIIS

The DIIS procedure to obtain the SCF solution depends on several parameters. Default values can be overruled with this block.

```
DIIS
   Adaptable Yes/No
   CHuge float
   CLarge float
   Condition float
   DiMix float
   DiMixMax float
   DiMixMin float
   NCycleDamp integer
   NVctrx integer
   Variant [DIIS | LISTi | LISTb | LISTd]
End
```

DIIS

> **Type** Block
>
> **Description** Parameters for the DIIS procedure to obtain the SCF solution

> **Adaptable**
>
> > **Type** Bool
> >
> > **Default value** Yes
> >
> > **Description** Change automatically the value of dimix during the SCF.

> **CHuge**
>
> > **Type** Float
> >
> > **Default value** 20.0
> >
> > **GUI name** No DIIS (but damping) when coefs >
> >
> > **Description** When the largest coefficient in the DIIS expansion exceeds this value, damping is applied

> **CLarge**
>
> > **Type** Float
> >
> > **Default value** 20.0
> >
> > **GUI name** Reduce DIIS space when coefs >
> >
> > **Description** When the largest DIIS coefficient exceeds this value, the oldest DIIS vector is removed and the procedure re-applied

> **Condition**
>
> > **Type** Float
> >
> > **Default value** 1000000.0
> >
> > **Description** The condition number of the DIIS matrix, the largest eigenvalue divided by the smallest, must not exceed this value. If this value is exceeded, this vector will be removed.

> **DiMix**
>
> > **Type** Float

Default value 0.2

GUI name Bias DIIS towards latest vector with

Description Mixing parameter for the DIIS procedure

DiMixMax

Type Float

Default value -1.0

Description For adaptive diis: A negative value means automatic, see DiMixatnvctrx. If positive it is an absolute upper bound for (adaptive) dimix

DiMixMin

Type Float

Default value 0.01

Description An absolute lower bound for adaptive dimix.

NCycleDamp

Type Integer

Default value 1

GUI name Do not start DIIS before cycle

Description Number of initial iterations where damping is applied, before any DIIS is considered

NVctrx

Type Integer

Default value 20

GUI name Size of DIIS space

Description Maximum number of DIIS expansion vectors

Variant

Type Multiple Choice

Default value DIIS

Options [DIIS, LISTi, LISTb, LISTd]

Description Which variant to use. In case of problematic SCF convergence, first try MultiSecant, and if that does not work the LISTi is the advised method. Note: LIST is computationally more expensive per SCF iteration than DIIS.

4.6.4 Multisecant

For more detais on the multisecant method see ref[1].

---

[1] L. D. Marks and D. R. Luke, *Robust mixing for ab initio quantum mechanical calculations*, Phys. Rev. B 78, 075114 (2008) (https://doi.org/10.1103/PhysRevB.78.075114)

```
MultiSecantConfig
   CMax float
   InitialSigmaN float
   MaxSigmaN float
   MaxVectors integer
   MinSigmaN float
End
```

MultiSecantConfig

>>> **Description** Maximum number of previous cycles to be used

>> **MinSigmaN**

>>> **Type** Float

>>> **Default value** 0.01

>>> **GUI name** Min

>>> **Description** Lower bound for the SigmaN parameter

4.6.5 MultiStepper

The MultiStepper introduces the concept of alternating between different steppers (methods). Methods are not switched at every SCF cycle, but rather after a sequence of them, called a stint. At the end of a stint it is considered whether it makes sense to try another stepper.

The key component is the Stepper. This wraps the type of the Stepper, say DIIS or SimpleMixing. Another important component is the MixAdapter. A step is controlled by a mix factor σ, also often called greed. The next guess density is a linear combination of previous input and output densities

$\rho^{\text{guess}} = \sum_i c_{i-1}^N (\rho_i^{\text{in}} + \sigma(\rho_i^{\text{out}} - \rho_i^{\text{in}}))$

The larger the mix factor the more aggressive the algorithm. Choosing it too small may simply stall the progress and choosing it too large can cause the error to grow. That is why using a MixAdapter is useful. It tries to predict a reasonable mix value, based on the progress of the error and also based on the number of previous iterations N that can be used without running into numerical problems.

A whole SCFMultiStepper block can be loaded from a file as a preset, and many reside in `$AMSHOME/data/presets/multi_stepper`. Normal users are not recommended to try to improve the standard preset. Which preset to loaded is controlled by the `SCF%MultiStepperPresetPath` key, and this may be an absolute path to your own preset.

The the log file (ams.log) shows the active stepper and mix factor.

```
<Nov22-2022> <15:24:28>  cyc=  0 err=0.00E+00 cpu=  75s ela=  76s

→ela=  58s fit=7.81E-02
```

From cycle 5 (cyc=5) on the second stepper is tried (meth=2), in this case because the error has grown too much since the start. Furthermore it restarts from the first density, not shown in the log file, using only one older density (nvec=1). Note that the second stepper starts with using a much more conservative mix factor (mix=0.006).

   End
End
```

SCF

SCFMultiStepper

Type Block

Description To solve the self-consistent problem multiple steppers can be tried during stints using the ones that give the best progress.

AlwaysChangeStepper

Type Bool

Default value No

Description When the progress is fine there is no reason to change the stepper. In practice this is always set to true, because also the Stepper%ExpectedSlope can be used to achieve similar behavior.

ErrorGrowthAbortFactor

Type Float

Default value 1000.0

Description Abort stint when the error grows too much, compared to the error at the start of the stint.

FractionalStepFactor

> **Type** Float
>
> **Default value** -1.0
>
> **Description** Multiply the step by this factor. If smaller than zero this is not used.

MinStintCyclesForAbort

> **Type** Integer
>
> **Default value** 0
>
> **Description** Look at ErrorGrowthAbortFactor only when a number of steps has been completed since the start of the stint. A value of 0 means always.

Stepper

> **Type** Block
>
> **Recurring** True
>
> **Description** ??

AbortSlope

> **Type** Float
>
> **Default value** 100.0
>
> **Description** If the slope (at the end of a stint) is larger than this: abort the stepper

DIISStepper

> **Type** Block
>
> **Description** DIIS stepper

EDIISAlpha

> **Type** Float
>
> **Default value** 0.01
>
> **Description** The extra energy vector is weighed by this factor. .

MaxCoefficient

> **Type** Float
>
> **Default value** 20.0
>
> **Description** The largest allowed value of the expansion coefficients. If exceed the number of vectors is reduces until the criterion is met.

MaxVectors

> **Type** Integer
>
> **Default value** 10
>
> **Description** Maximum number of previous densities to be used (size of the history).

MinVectors

Type Integer

Default value -1

Description Try to prevent to make nVectors shrink below this value, by allowing for significantly larger coefficents.

Mix

Type Float

Default value 0.2

Description Also known as greed. It determines the amount of output density to be used. May be changed by the MixAdapter.

ErrorGrowthAbortFactor

Type Float

Default value -1.0

Description Abort stint when the error grows too much, compared to the error at the start of the stint. Overides global ErrorGrowthAbortFactor when set to a value > 0

ExpectedSlope

Type Float

Default value -100.0

Description If the slope of the total SCF is better than this keep on going.

FractionalStepFactor

Type Float

Default value -1.0

Description Multiply the step by this factor. If smaller than zero this is not used.

MaxInitialError

Type Float

Description Only use the stepper when error is smaller than this.

MaxIterationNumber

Type Integer

Default value -1

Description Stepper will only be active for iterations smaller than this number. (Negative value means: Ignore this option)

MaxStintNumber

Type Integer

Default value -1

Description Stepper will only be active for stints smaller than this number. (Negative value means: Ignore this option)

MinInitialError

Type Float

Description Only use the stepper when error is larger than this.

MinIterationNumber

> **Type** Integer
>
> **Default value** -1
>
> **Description** Stepper will only be active for iterations larger than this number.

MinStintCyclesForAbort

> **Type** Integer
>
> **Default value** 0
>
> **Description** Look at ErrorGrowthAbortFactor only when a number of steps has been completed since the start of the stint. A value of 0 means always. Overides global value.

MinStintNumber

> **Type** Integer
>
> **Default value** -1
>
> **Description** Stepper will only be active for stints larger than this number.

MixAdapter

> **Type** Block
>
> **Description** Generic mix adapter

> **ErrorGrowthPanicFactor**
>
> > **Type** Float
> >
> > **Default value** 10.0
> >
> > **Description** When the error increases more than this factor, this mix is reduced a lot.

> **GrowthFactor**
>
> > **Type** Float
> >
> > **Default value** 1.1
> >
> > **Description** When the mix is considered too low it is multiplied by this factor. Otherwise it is divided by it.

> **MaxMix**
>
> > **Type** Float
> >
> > **Default value** 0.3
> >
> > **Description** Do not grow the mix above this value.

> **MinMix**
>
> > **Type** Float
> >
> > **Default value** 0.1
> >
> > **Description** Do not shrink the mix below this value.

> **NTrialMixFactors**
>
> > **Type** Integer
> >
> > **Default value** 3
> >
> > **Description** Only used with Type=Trial. Must be an odd number.

TrialMode

> **Type** Multiple Choice
>
> **Default value** CurrentMixCentered
>
> **Options** [CurrentMixCentered, FullRange]
>
> **Description** How are the NTrialMixFactors chosen?

Type

> **Type** Multiple Choice
>
> **Default value** Error
>
> **Options** [Error, Energy, UnpredictedStep, Trial]
>
> **Description** Adapt the mix factor based on the observed progress (slope).

MixStepper

> **Type** Block
>
> **Description** Simple mixing stepper, only using the previous (in/out) denstity.

Mix

> **Type** Float
>
> **Default value** 0.1
>
> **Description** ???.

MultiSecantStepper

> **Type** Block
>
> **Description** Multi secant stepper.

MaxCoefficient

> **Type** Float
>
> **Default value** 20.0
>
> **Description** ???.

MaxVectors

> **Type** Integer
>
> **Default value** 10
>
> **Description** ???.

Mix

> **Type** Float
>
> **Default value** 0.2
>
> **Description** ???.

Variant

> **Type** Multiple Choice
>
> **Default value** MSB2
>
> **Options** [MSB1, MSB2, MSR1, MSR1s]

> **Description** There are several version of the Multi secant method.

> **StintLength**

>> **Type** Integer

>> **Description** Override global StintLength.

> **StintLength**

>> **Type** Integer

>> **Default value** 10

>> **Description** A stepper is active during a number of SCF cycles, called a stint.

> **UsePreviousStintForErrorGrowthAbort**

>> **Type** Bool

>> **Default value** No

>> **Description** The error is normally checked against the first error of the stint. With this option that will be the one from the previous stint, if performed with the same stepper.

4.6.6 DIRIS

In the DIRIS block, which has the same options as the `DIIS` block, you can specify the DIIS options to be used in the Dirac subprogram, for numerical single atom calculations, which constructs the radial tables for the NAOs.

4.7 MBPT scheme

Note: This page describes technical aspects of the MBPT (Many-Body Perturbation Theory) module which is used in double-hybrid and MP2, RPA, GW and GW-BSE calculations. In order to use double-hybrids, MP2 or RPA in your calculation you should request it in the *XC input block* (page 13). In order to perform a GW calculation, you should request it in the *GW input block* (page 116).

BAND implements RPA, GW, and SOS-MP2 (spin-opposite-scaled) using a newly designed algorithm which in all cases scales quadratically with system size[13]. Full MP2 is at the moment only implemented using the canonical RI-algorithm which scales to the fifth power with system size. Thus, we strongly discourage using full MP2 or double-hybrids employing full MP2 for system larger than 1000-1500 basis functions. At the moment BAND features a large number of double-hybrids using SOS-MP2 only (For a list of implemented functionals see *XC input block* (page 13)) which are significantly faster than conventional double-hybrids while offering the same level of accuracy[2].

GW, MP2, RPA and double-hybrid functionals can be used icw scalar relativistic effects within the `ZORA`, `X2C`, or `RA-X2C` formalism. In BAND2022 in case of ZORA by default the so called scaled ZORA orbital energies are used in the MBPT expressions.

The Formalism used in the double-hybrid calculation can be changed using the Formalism key. By default, BAND selects the most appropriate algorithm for your system and functional.

[3] A. Förster, L. Visscher, *Low-order scaling |G0W0| by pair atomic density fitting*, Journal of Chemical Theory and Computation 16 (12), 7381 (2020) (https://doi.org/10.1021/acs.jctc.0c00693)

[2] A. Förster, L. Visscher, *Double hybrid DFT calculations with Slater type orbitals*, Journal of Computational Chemistry 41 1660-1684 (2020) (https://doi.org/10.1002/jcc.26209)

The calculation of the independent-particle polarizability or Kohn-Sham density response function in imaginary time is the key step in SOS-MP2, RPA and GW. The equations are solved in the atomic orbital basis exploiting sparsity via advanced density fitting techniques (so-called pair-atomic resolution of the identity or pair-atomic density fitting)[?]. In case of a SOS-MP2 or RPA calculation, the polarizability is than contracted with the Coulomb potential. For SOS-MP2, the correlation energy is then immediately evaluated in imaginary time while in a RPA calculation the product of Coulomb potential and polarizability is Fourier transformed to the imaginary frequency axis where the correlation energy is evaluated using a matrix logarithm. In a GW calculation, the polarizability is Fourier transformed to the imaginary frequency axis as well where the so-called screened interaction is calculated. The QP states are then evaluated along the real-frequency axis using analytical continuation techniques.

4.7.1 Recommended numerical settings

For all calculations using the MBPT scheme (which includes GW, GW-BSE, RPA, MP2, and double hybrids), we recommend to consider the following points:

Dependency

In BAND a similar method is implemented as in the RIHARTREEFOCK scheme to improve stability of the results with the subkey DEPENDENCY of the key MBPT:

```
MBPT
   Dependency Yes/No
End
```

MBPT

    Dependency

        Type Bool

        Default value Yes

        Description If true, to improve numerical stability, almost linearly-dependent combination of basis functions are removed from the Green's function that are used in the MBPT equations. Disabeling this key is stringly discouraged. Its value can however be changed. The key to adjust this value is RiHartreeFock%DependencyThreshold

In addition one may remove linear dependencies in the basis set, by using the `Dependency` key. The following is recommended

```
Dependency
   AllowBasisDependency True
   Basis 1e-4
End
```

in case a large auxiliary fit set is used

Starting from AMS2022 BAND will use a `Dependency   bas=5e-3` and `RIHartreeFock DependencyThreshold=5e-3` in case of (any variant of) GW and GW-BSE. One can override these values in the input.

Numerical Quality

Augmented basis sets: Numerical quality should be `VeryGood`
Non-augmented basis sets, TZ: Numerical quality should range from `Normal` to `VeryGood`
Non-augmented basis sets, QZ: Numerical quality should range from `Good` to `VeryGood`

There is also the option to choose a different numerical quality for the MBPT and the preceding DFT calculation:

```
MBPT
   NumericalQuality Good
END
```

sets the numerical quality to Good only for the MBPT calculation.

The sizes of the imaginary time and imaginary frequency grids can be controlled with the `nTime` and `nFrequency` keys. For example:

```
MBPT
   nTime 32
   nFrequency 32
END
```

In case of SOS-MP2, `nFrequency` is ignored. The numerical quality automatically sets the number of grid points for imaginary time and frequency integration in case of a GW or RPA calculation:

Numerical quality	Number of points
VERYBASIC	8
BASIC	12
NORMAL	16
GOOD	20
VERYGOOD	24
EXCELLENT	32

For a MP2 or double hybrid calculation, see default is always 9 points, independently of the numerical quality. Note, that the requirements for this parameter are in general lower than for a GW or RPA calculation. Starting from AMS2022, the number of points is automatically adjusted in SOS-MP2 as well.

Note the following: The number of points actually used in a calculation can differ. At runtime, the MBPT algorithm decides what is the maximum number of integration points which is reasonable to use. So the actual number of points which has been used will be equal or smaller. In case the number of points is set by hand, some info is printed in the output. In case of a GW calculation, the numbers of points can also be found in band.rkf file in the `GW` section under the names `nTime` and `nFrequency`.

Changing the defaults can be necessary in case your system contains 4th row elements or heavier and/or your basis set is very large and/or your system has a very small HOMO-LUMO gap. For a GW calculation, 24 points should be sufficient for 5th row elements. 32 points might be required for 6th row elements. The maximum number of points which can be used is 42. For a MP2 calculation, 16 points will usually be sufficient if your systems contains 4th row elements, and 20 points will usually suffice in case of 5th row elements. Note, that also a very small HOMO-LUMO.

```
MBPT
   Formalism [Auto | RI | LT | All]
   FrequencyGridType [LeastSquare | GaussLegendre]
   nTime integer
   nFrequency integer
   nLambda integer

   IntegrationQuality [VeryBasic | Basic | Normal | Good | VeryGood]
   ThresholdQuality [VeryBasic | Basic | Normal | Good | VeryGood | Excellent]
   Dependency Yes/No
   UseScaledZORA Yes/No
```

```
    SigmaFunctionalParametrization [W1 | W2 | S1 | S2 | S1re]
End
```

MBPT

> **Type** Block
>
> **Description** Technical aspects of the MP2 algorithm.

Formalism

> **Type** Multiple Choice
>
> **Default value** Auto
>
> **Options** [Auto, RI, LT, All]
>
> **Description** Specifies the formalism for the calculation of the MP2 correlation energy.
>
>> 'LT' means Laplace Transformed MP2 (also referred to as AO-PARI-MP2),
>>
>> 'RI' means that a conventional RI-MP2 is carried out.
>>
>> If 'Auto', LT will be used in case of DOD double hybrids and SOS MP2, and RI will be used in all other cases.
>>
>> 'All' means that both RI and LT formalisms are used in the calculation.
>>
>> For a RPA or GW calculation, the formalism is always LT, irrespective of the formalism specified with this key.

FrequencyGridType

> **Type** Multiple Choice
>
> **Default value** LeastSquare
>
> **Options** [LeastSquare, GaussLegendre]
>
> **Description** Use Gauss-legendre grid for imaginary frequency integration in RPA and GW calculations instead of the usually used Least-Square optimized ones. Has the advantage that it can be systematically converged and an arbitrary number of grid points can be used. Typically more grid points will be needed to get the same level of accuracy. However, the convergence of the results with the size of the grid can be more systematic. These grids can only be used when Formalism is set to RI.

nTime

> **Type** Integer
>
> **GUI name** Number of time points
>
> **Description** Number of imaginary time points (only relevant in case the Laplace Transformed (LT) formalism is used).
>
>> In the many-body-perturbation theory module in ADF, the polarizability (or Kohn-Sham density response function) is evaluated in imaginary time to exploit sparsity in the AO basis. For MP2, this is often referred to as a Laplace transform. For MP2, 9 points are the default. This is a safe choice, guaranteeing accuracies higher than 1 Kj/mol for most systems (For many simple organic systems, 6 points are sufficient for good accuracy).
>>
>> Only for systems with a very small HOMO-LUMO gap or low-lying core states (heavy elements starting from the 4th row of the periodic table) more points might be necessary.

In principle, the same considerations apply for RPA and GW as well, however, the accuracy requirements are somewhat higher and 12 point are the default for RPA. In a GW calculation, the number of points is adjusted according to the numerical quality. Using less than 9 points is strongly discouraged except for the simplest molecules.

In ADF2019, it can happen that the algorithm determining the imaginary time grid does not converge. In this case, the usual reason is that the number of points is too small and more points need to be specified. Starting from AMS2020, this does not happen any more. In case the imaginary time grid does not converge, the number of points is automatically adjusted until it does.

The computation time of AO-PARI-MP2, RPA, and GW scales linearly with the number of imaginary time points.

nFrequency

> **Type** Integer
>
> **Default value** 12
>
> **GUI name** Number of frequency points
>
> **Description** Number of imaginary frequency points. This key is only relevant for RPA and GW and will be ignored if used in an AO-PARI-MP2 calculation. 12 Points is the default for a RPA calculation. It is technically possible to use a different number of imaginary frequency points than for imaginary time. The maximum number of points which can be requested for imaginary frequency integration is 42. Important note: The computation time and memory requirements roughyl scale linearly with the number of imaginary frequency points. However, memory can be an issue for RPA and GW when the number of imaginary frequency points is high. In case a job crashes, it is advised to increase the number of nodes since the necessary memory distributes over all nodes.

nLambda

> **Type** Integer
>
> **Default value** 1
>
> **GUI name** Number of lambda points
>
> **Description** Size of coupling constant integration grid for SOSEX variants in RPA. Default is 4 points

FitSetQuality

> **Type** Multiple Choice
>
> **Default value** Auto
>
> **Options** [Auto, VeryBasic, Basic, Normal, Good, VeryGood]
>
> **Description** Specifies the fit set to be used in the MBPT calculation.
>
> 'Normal' quality is generally sufficient for basis sets up to and including TZ2P.
>
> For larger basis sets (or for benchmarking purposes) a 'VeryGood' fit set is recommended. Note that the FitSetQuality heavily influences the computational cost of the calculation.
>
> If not specified or 'Auto', the RIHartreeFock%FitSetQuality is used.

IntegrationQuality

> **Type** Multiple Choice
>
> **Options** [VeryBasic, Basic, Normal, Good, VeryGood]

Description Specifies the integration quality to be used in the MBPT calculation. If not specified, the RIHartreeFock%IntegrationQuality is used.

ThresholdQuality

> **Type** Multiple Choice
>
> **Options** [VeryBasic, Basic, Normal, Good, VeryGood, Excellent]
>
> **Description** Controls the distances between atomic centers for which the product of two basis functions is not fitted any more. Especially for spatially extended, large systems, 'VERYBASIC' and 'BASIC' can lead to large computational savings, but the fit is also more approximate. If not specified, the RIHartreeFock%ThresholdQuality is used.

Dependency

> **Type** Bool
>
> **Default value** Yes
>
> **Description** If true, to improve numerical stability, almost linearly-dependent combination of basis functions are removed from the Green's function that are used in the MBPT equations. Disabeling this key is stringly discouraged. Its value can however be changed. The key to adjust this value is RiHartreeFock%DependencyThreshold

UseScaledZORA

> **Type** Bool
>
> **Default value** Yes
>
> **Description** If true, use the scaled ZORA orbital energies instead of the ZORA orbital energies in the MBPT equations.

SigmaFunctionalParametrization

> **Type** Multiple Choice
>
> **Default value** S1re
>
> **Options** [W1, W2, S1, S2, S1re]
>
> **Description** Only relevant if a sigma-functional calculation is performed. Possible choices for the parametrization of the sigma-functional. Not all options are supported for all functionals.

4.8 More Technical Settings

There are of course many other settings influencing the precision and performance. Usually the user does not need to care about them.

4.8.1 Linear Scaling

```
Tails
   Bas float
End
```

Tails

> **Type** Block
>
> **Description** Ignore function tails.

Bas

> **Type** Float
>
> **Default value** 1e-06
>
> **GUI name** Basis functions
>
> **Description** Cut off the basis functions when smaller than the specified threshold.

4.8.2 Dependency

```
Dependency
   AllowBasisDependency Yes/No
   Basis float
   Core float
   CoreValence float
   Fit float
End
```

Dependency

> **Type** Block
>
> **Description** Criteria for linear dependency of the basis and fit set

> **AllowBasisDependency**
>
> > **Type** Bool
> >
> > **Default value** Yes
> >
> > **Description** Project out the dependent part of the basis set (associated with small eigenvalues of the overlap matrix).

> **Basis**
>
> > **Type** Float
> >
> > **Default value** 1e-08
> >
> > **GUI name** Dependency criterion
> >
> > **Description** Criteria for linear dependency of the basis: smallest eigenvalue of the overlap matrix of normalized Bloch functions.

> **Core**
>
> > **Type** Float
> >
> > **Default value** 0.8
> >
> > **Description** The program verifies that the frozen core approximation is reasonable, by checking the smallest eigen value of the overlap matrix of the core (Bloch) orbitals (which should ideally be one) is bigger than this criterion.

> **CoreValence**
>
> > **Type** Float
> >
> > **Default value** 1e-05
> >
> > **Description** Criterion for dependency of the core functions on the valence basis. The maximum overlap between any two normalized functions in the two respective function spaces should not exceed 1.0-corevalence

Fit

> **Type** Float
>
> **Default value** 5e-06
>
> **Description** Criterion for dependency of the total set of fit functions. The value monitored is the smallest eigenvalue of the overlap matrix of normalized Bloch sums of symmetrized fit functions.

4.8.3 Screening

Band performs many lattice summations which are in practice truncated. The two prime examples are the construction of the Bloch basis and the calculation of the solvation potential. The precision of the lattice summations is controlled by the `Screening` key

```
Screening
   CutOff float
   DMadel float
   NoDirectionalScreening Yes/No
   RCelx float
   RMadel float
End
```

Screening

> **Type** Block
>
> **Description** For the periodic solvation potential and for the old (not default anymore) fitting method, BAND performs lattice summations which are in practice truncated. The precision of the lattice summations is controlled by the options in this block.

CutOff

> **Type** Float
>
> **Description** Criterion for negligibility of tails in the construction of Bloch sums. Default depends on Accuracy.

DMadel

> **Type** Float
>
> **Description** One of the parameters that define the screening of Coulomb-potentials in lattice sums. Depends by default on Accuracy, rmadel, and rcelx. One should consult the literature for more information

NoDirectionalScreening

> **Type** Bool
>
> **Description** Real space lattice sums of slowly (or non-) convergent terms, such as the Coulomb potential, are computed by a screening technique. In previous releases, the screening was applied to all (long-range) Coulomb expressions. Screening is only applied in the periodicity directions. This key restores the original situation: screening in all directions

RCelx

> **Type** Float
>
> **Description** Max. distance of lattice site from which tails of atomic functions will be taken into account for the Bloch sums. Default depends on Accuracy.

RMadel

>> **Type** Float
>>
>> **Description** One of the parameters that define screening of the Coulomb potentials in lattice summations. Depends by default on Accuracy, dmadel, rcelx. One should consult the literature for more information.

4.8.4 Direct (on the fly) calculation of basis and fit

BAND usually calculates basis functions and theirs derivatives on the fly. However, for small bulk systems it can be faster to write the information to disk. Then one can set the `DirectBas` key to false. (**Default = true**)

```
Programmer
   DirectBas bool
End
```

4.8.5 Fermi energy search

```
Fermi
   Delta float
   Eps float
   MaxTry integer
   RefinePostSCFFactor integer
End
```

Fermi

>> **Type** Block
>>
>> **Description** Technical parameter used in determining the Fermi energy, which is carried out at each cycle of the SCF procedure.

>> **Delta**
>>
>>>> **Type** Float
>>>>
>>>> **Default value** 0.0001
>>>>
>>>> **Description** Convergence criterion: upper and lower bounds for the Fermi energy and the corresponding integrated charge volumes must be equal within delta.

>> **Eps**
>>
>>>> **Type** Float
>>>>
>>>> **Default value** 1e-10
>>>>
>>>> **Description** After convergence of the Fermi energy search procedure, a final estimate is defined by interpolation and the corresponding integrated charge volume is tested. It should be exact, to machine precision. Tested is that it deviates not more than eps.

>> **MaxTry**
>>
>>>> **Type** Integer
>>>>
>>>> **Default value** 15

Description Maximum number of attempts to locate the Fermi energy. The procedure is iterative in nature, narrowing the energy band in which the Fermi energy must lie, between an upper and a lower bound. If the procedure has not converged sufficiently within MaxTry iterations, the program takes a reasonable value and constructs the charge density by interpolation between the functions corresponding to the last used upper and lower bounds for the Fermi energy.

RefinePostSCFFactor

Type Integer

Description Use a finer k-grid after the scf to calculate a refined fermi level. Makes only sense for metals. Works like DoubleCount. Use 1,2,3

4.8.6 Block size

```
CPVector integer
```

CPVector

Type Integer

Default value 128

GUI name Vectorlength (blocksize)

Description The code is vectorized and this key can be used to set the vector length

```
KGrpX integer
```

KGrpX

Type Integer

Default value 5

GUI name Number of K-points at once

Description Absolute upper bound on the number of k-points processed together. This only affects the computational performance.

SPECTROSCOPY AND PROPERTIES

5.1 Frequencies and Phonons

Frequencies and Phonons and can be computed via numerical differentiation by the AMS diver. See the Normal Modes section or the Phonon section of the AMS manual.

Several thermodynamic properties, such as Zero-point Energy, Internal Energy, Entropy, Free Energy and Specific Heat are computed by default when calculating Phonons.

5.2 Elastic Tensor

The elastic tensor (and related elastic properties such as Bulk modulus, Shear modulus and Young modulus) can be computed via numerical differentiation by AMS. See the Elastic Tensor section of the AMS manual.

When calculating the elastic tensors using Band one should disable *Symmetry* (page 163).

5.3 Optical Properties: Time-Dependent Current DFT

Time-Dependent Current Density Functional Theory (**TD-CDFT**) is a theoretical framework for computing optical response properties, such as the frequency-dependent dielectric function.

In this section, the TD-CDFT implementation for extended systems (1D, 2D and 3D) in BAND is described. The input keys are described in *NewResponse* (page 97) or in *OldResponse* (page 102).

Some examples are available in the $AMSHOME/examples/band directory and are discussed in the Examples section.

- Tutorial: Silicon (OldResponse)

- Tutorial: MoS2 Monolayer (NewResponse)

- *Example: TD-CDFT for bulk diamond (OldResponse)* (page 257)

5.3.1 Insulators, semiconductors and metals

The TD-CDFT module enables the calculation of real and imaginary parts of the material property tensor $\chi_e(\omega)$, called the **electric susceptibility**. The electric susceptibility is related to the macroscopic **dielectric function**, $\varepsilon_M(\omega)$.

For semi-conductors and insulator, for which the bands are either fully occupied or fully unoccupied, the dielectric function $\varepsilon_M(\omega)$ comprises only of the so called interband component:

$$\varepsilon_M(\omega) = 1 + 4\pi\chi_e(\omega)$$

In general $\chi_e(\omega)$ and $\varepsilon_M(\omega)$ are tensors. They, however, simplify to scalars in isotropic systems.

For metals, for which partially-occupied bands exist, there is a so called intraband component arising due to transitions within a partially-occupied band:

$$\varepsilon_M(\omega) = 1 + 4\pi\chi_e(\omega) - 4\pi i\sigma_e(\omega)/\omega$$

5.3.2 Frequency dependent kernel

It is known that the exact Vignale-Kohn (VK) kernel greatly improves the static polarizabilities of infinite polymers and nanotubes (see reference (https://doi.org/10.1063/1.2102899)), but gives bad results for the optical spectra of semi-conductors and metals. For the low frequency part one needs a frequency dependent kernel, since Drude-like tails are completely absent in the adiabatic local density approximation (ALDA). With a modified VK kernel, which neglects μ_{xc} so that it reduces to the ALDA form in the static limit (see reference (https://doi.org/10.1103/PhysRevB.74.245117)), much better results can be obtained. BAND currently only supports the modified VK kernel in either the QV or CNT parametrization, and it should **only be used for metals**.

5.3.3 EELS

From the macroscopic dielectric function it is possible to calculate the electron energy loss function (EELS). In transmission EELS one studies the inelastic scattering of a beam of high energy electrons by a target. The scattering rates obtained in these experiments are related to the dynamical structure factor $S(q,\omega)$ [A1]. In the special case with wavevector $q = 0$, $S(q,\omega)$ is related to the longitudinal macroscopic dielectric function. This is the long-wave limit of EELS. For isotropic system the dielectric function is simply a scalar $(1/3\mathrm{Tr}(\varepsilon_M(\omega)))$. In this case the long-wave limit of the electron energy loss function assumes the trivial form

$$\lim_{q\to 0} 2\pi \frac{S(q,\omega)}{q^2 V} = \frac{\varepsilon_2}{\varepsilon_1^2 + \varepsilon_2^2}$$

with ε_1 and ε_2 as real and imaginary part of the dielectric function.

References

The three related Ph.D. theses, due to F. Kootstra (on TD-DFT for insulators), P. Romaniello (on TD-CDFT for metals), and A. Berger (on the Vignale-Kohn functional in extended systems) contain much background information, and can be downloaded from the SCM website (http://www.scm.com).

The most relevant publications on this topic due to the former "Groningen" group of P.L. de Boeij are[1234].

5.3.4 Input Options

In the 2017 release of BAND there are two implementations of the TD-CDFT formalism. The original implementation, relying on obsolete algorithms of BAND, is accessible via the *OldResponse* (page 102) key block. The new code section, relying on more modern algorithms of BAND, is accessible via the *NewResponse* (page 97), *NewResponseSCF* (page 99) and *NewResponseKSpace* (page 101) key blocks. The differences between the two flavors are summarized in the following table:

	OldResponse	NewResponse
3D-systems	yes	yes
2D-systems	no	yes
1D-systems	(yes)	yes
Semiconductors	yes	yes
Metals	yes	(yes)
ALDA	yes	yes
Vignale-Kohn	yes	no
Berger2015 (3D)	yes	yes
Scalar ZORA	yes	yes
Spin Orbit ZORA	yes	no

Besides these differences, one should not expect both flavors to give the exact same result, if the reciprocal space limit is not reached! This can be explained by different approaches to evaluate the integration weights of single-particle transitions in reciprocal space.

> **Attention:** Response properties **converge slowly** with respect to k-space sampling (number of k-points). **Always check the convergence of** ε_M **with respect to** *K-Space* (page 57) **options!!!**

NewResponse

The dielectric function is computed when the key block *NewResponse* (page 97) is present in the input. Several important settings can be defined in this key block.

Additional details can be specified via the *NewResponseKSpace* (page 101) and *NewResponseSCF* (page 99) blocks.

```
NewResponse
   NFreq integer
   FreqLow float
   FreqHigh float
   EShift float
   ActiveESpace float
   DensityCutOff float
   ActiveXYZ string
End
```

NewResponse

> **Type** Block
>
> **Description** The TD-CDFT calculation to obtain the dielectric function is computed when this block is present in the input. Several important settings can be defined here.

NFreq

> **Type** Integer

Default value 5

Description Number of frequencies for which a linear response TD-CDFT calculation is performed.

FreqLow

Type Float

Default value 1.0

Unit eV

Description Lower limit of the frequency range for which response properties are calculated. (omega_{low})

FreqHigh

Type Float

Default value 3.0

Unit eV

Description Upper limit of the frequency range for which response properties are calculated (omega_{high}).

EShift

Type Float

Default value 0.0

Unit eV

GUI name Shift

Description Energy shift of the virtual crystal orbitals.

ActiveESpace

Type Float

Default value 5.0

Unit eV

GUI name Active energy space

Description Modifies the energy threshold (DeltaE^{max}_{thresh} = omega_{high} + ActiveESpace) for which single orbital transitions (DeltaEpsilon_{ia} = Epsilon_{a}^{virtual} - Epsilon_{i}^{occupied}) are taken into account.

DensityCutOff

Type Float

Default value 0.001

GUI name Volume cutoff

Description For 1D and 2D systems the unit cell volume is undefined. Here, the volume is calculated as the volume bordered by the isosurface for the value DensityCutoff of the total density.

ActiveXYZ

Type String

Default value t

> **Description** Expects a string consisting of three letters of either 'T' (for true) or 'F' (for false) where the first is for the X-, the second for the Y- and the third for the Z-component of the response properties. If true, then the response properties for this component will be evaluated.

```
NewResponseSCF
   Bootstrap integer
   COApproach Yes/No
   COApproachBoost Yes/No
   Criterion float
   DIIS
      Enabled Yes/No
      MaxSamples integer
      MaximumCoefficient float
      MinSamples integer
      MixingFactor float
   End
   LowFreqAlgo Yes/No
   NCycle integer
   XC integer
End
```

NewResponseSCF

> **Type** Block
>
> **Description** Details for the linear-response self-consistent optimization cycle. Only influencing the NewResponse code.

Bootstrap

> **Type** Integer
>
> **Default value** 0
>
> **Description** defines if the Berger2015 kernel (Bootstrap 1) is used or not (Bootstrap 0). If you chose the Berger2015 kernel, you have to set NewResponseSCF%XC to '0'. Since it shall be used in combination with the bare Coulomb response only. Note: The evaluation of response properties using the Berger2015 is recommend for 3D systems only!

COApproach

> **Type** Bool
>
> **Default value** Yes
>
> **Description** The program automatically decides to calculate the integrals and induced densities via the Bloch expanded atomic orbitals (AO approach) or via the cyrstal orbitals (CO approach). The option COApproach overrules this decision.

COApproachBoost

> **Type** Bool
>
> **Default value** No
>
> **GUI name** CO Approach Boost
>
> **Description** Keeps the grid data of the Crystal Orbitals in memory.
>
> Requires significantly more memory for a speedup of the calculation. One might have to use multiple computing nodes to not run into memory problems.

Criterion

Type Float

Default value 0.001

Description For the SCF convergence the RMS of the induced density change is tested. If this value is below the Criterion the SCF is finished.

Furthermore, one can find the calculated electric susceptibility for each SCF step in the output and can therefore decide if the default value is too loose or too strict.

DIIS

Type Block

Description Parameters influencing the DIIS self-consistency method

Enabled

Type Bool

Default value Yes

Description If not enabled simple mixing without DIIS acceleration will be used.

MaxSamples

Type Integer

Default value 10

Description Specifies the maximum number of samples considered during the direct inversion of iteration of subspace (DIIS) extrapolation of the atomic charges during the SCC iterations. A smaller number of samples potentially leads to a more aggressive convergence acceleration, while a larger number often guarantees a more stable iteration. Due to often occurring linear dependencies within the set of sample vectors, the maximum number of samples is reached only in very rare cases.

MaximumCoefficient

Type Float

Default value 10.0

Description When the diis expansion coefficients exceed this threshold, the solution is rejected. The vector space is too crowded. The oldest vector is discarded, and the expansion is re-evaluated.

MinSamples

Type Integer

Default value -1

Description When bigger than one, this affects the shrinking of the DIIS space on linear depence. It will not reduce to a smaller space than MinSamples unless there is extreme dependency.

MixingFactor

Type Float

Default value 0.2

Description The parameter used to mix the DIIS linear combination of previously sampled atomic charge vectors with an analogous linear combination of charge vectors resulting from population analysis combination. It can assume real values between 0 and 1.

LowFreqAlgo

>> **Type** Bool
>>
>> **Default value** Yes
>>
>> **GUI name** Low Frequency Algorithm
>>
>> **Description** Numerically more stable results for frequencies lower than 1.0 eV. Note: for a graphene monolayer the conical intersection results in a very small band gap (zero band gap semi-conductor). This leads ta a failing low frequency algorithm. One can then chose to use the algoritm as originally proposed by Kootstra by setting the input value to *false*. But, this can result in unreliable results for frequencies lower than 1.0 eV!

NCycle

>> **Type** Integer
>>
>> **Default value** 20
>>
>> **GUI name** Cycles
>>
>> **Description** Number of SCF cycles for each frequency to be evaluated.

XC

>> **Type** Integer
>>
>> **Default value** 1
>>
>> **Description** Influences if the bare induced Coulomb response (XC 0) is used for the effective, induced potential or the induced potential derived from the ALDA kernel as well (XC 1).

```
NewResponseKSpace
   Eta float
   SubSimp integer
End
```

NewResponseKSpace

>> **Type** Block
>>
>> **Description** Modify the details for the integration weights evaluation in reciprocal space for each single-particle transition. Only influencing the NewResponse code.

Eta

>> **Type** Float
>>
>> **Default value** 1e-05
>>
>> **Description** Defines the small, finite imaginary number i*eta which is necessary in the context of integration weights for single-particle transitions in reciprocal space.

SubSimp

>> **Type** Integer
>>
>> **Default value** 3
>>
>> **Description** determines into how many sub-integrals each integration around a k point is split. This is only true for so-called quadratic integration grids. The larger the number the better the convergence behavior for the sampling in reciprocal space. Note: the computing time for the weights is linear for 1D, quadratic for 2D and cubic for 3D!

OldResponse

```
OldResponse
   Berger2015 Yes/No
   CNT Yes/No
   CNVI float
   CNVJ float
   Ebndtl float
   Enabled Yes/No
   Endfr float
   Isz integer
   Iyxc integer
   NewVK Yes/No
   Nfreq integer
   QV Yes/No
   Shift float
   Static Yes/No
   Strtfr float
End
```

OldResponse

>>> **Type** Block
>>>
>>> **Description** Options for the old TD-CDFT implementation.

> **Berger2015**

>>> **Type** Bool
>>>
>>> **Default value** No
>>>
>>> **Description** Use the parameter-free polarization functional by A. Berger (Phys. Rev. Lett. 115, 137402). This is possible for 3D insulators and metals. Note: The evaluation of response properties using the Berger2015 is recommend for 3D systems only!

> **CNT**

>>> **Type** Bool
>>>
>>> **Description** Use the CNT parametrization for the longitudinal and transverse kernels of the XC kernel of the homogeneous electron gas. Use this in conjunction with the NewVK option.

> **CNVI**

>>> **Type** Float
>>>
>>> **Default value** 0.001
>>>
>>> **Description** The first convergence criterion for the change in the fit coefficients for the fit functions, when fitting the density.

> **CNVJ**

>>> **Type** Float
>>>
>>> **Default value** 0.001
>>>
>>> **Description** the second convergence criterion for the change in the fit coefficients for the fit functions, when fitting the density.

> **Ebndtl**

>>> **Type** Float

Default value 0.001

Unit Hartree

Description the energy band tolerance, for determination which routines to use for calculating the numerical integration weights, when the energy band posses no or to less dispersion.

Enabled

>   **Type** Bool
>
>   **Default value** No
>
>   **Description** If true, the response function will be calculated using the old TD-CDFT implementation

Endfr

>   **Type** Float
>
>   **Default value** 3.0
>
>   **Unit** eV
>
>   **Description** The upper bound frequency of the frequency range over which the dielectric function is calculated

Isz

>   **Type** Integer
>
>   **Default value** 0
>
>   **Description** Integer indicating whether or not scalar zeroth order relativistic effects are included in the TDCDFT calculation. 0 = relativistic effects are not included, 1 = relativistic effects are included. The current implementation does NOT work with the option XC%SpinOrbitMagnetization equal NonCollinear

Iyxc

>   **Type** Integer
>
>   **Default value** 0
>
>   **Description** integer for printing yxc-tensor (see http://aip.scitation.org/doi/10.1063/1.1385370). 0 = not printed, 1 = printed.

NewVK

>   **Type** Bool
>
>   **Description** Use the slightly modified version of the VK kernel (see https://aip.scitation.org/doi/10.1063/1.1385370). When using this option one uses effectively the static option, even for metals, so one should check carefully the convergence with the KSPACE parameter.

Nfreq

>   **Type** Integer
>
>   **Default value** 5
>
>   **Description** the number of frequencies for which a linear response TD-CDFT calculation is performed.

QV

>   **Type** Bool

Description Use the QV parametrization for the longitudinal and transverse kernels of the XC kernel of the homogeneous electron gas. Use this in conjunction with the NewVK option. (see reference).

Shift

>   **Type** Float
>
>   **Default value** 0.0
>
>   **Unit** eV
>
>   **Description** energy shift for the virtual crystal orbitals.

Static

>   **Type** Bool
>
>   **Description** An alternative method that allows an analytic evaluation of the static response (normally the static response is approximated by a finite small frequency value). This option should only be used for non-relativistic calculations on insulators, and it has no effect on metals. Note: experience shows that KSPACE convergence can be slower.

Strtfr

>   **Type** Float
>
>   **Default value** 1.0
>
>   **Unit** eV
>
>   **Description** is the lower bound frequency of the frequency range over which the dielectric function is calculated.

5.4 ESR/EPR

BAND is capable to calculate electron paramagnetic resonance (EPR) parameters for paramagnetic defects in solids: hyperfine A-tensor and the Zeeman g-tensor.

The implementation of EPR parameters in BAND is described in the publications by Kadantsev and co-workers[1] and[2].

Hyperfine A-tensor

The A-tensor is implemented within the non-relativistic and scalar relativistic, spin-polarized Kohn-Sham scheme.

```
ATensor
   Enabled Yes/No
End
```

ATensor

>   **Type** Block
>
>   **Description** Hyperfine A-tensor.

>   **Enabled**

>   **Type** Bool

---

[1] E.S. Kadantsev and T. Ziegler, *Implementation of a Density Functional Theory-Based Method for the Calculation of the Hyperfine A-tensor in Periodic Systems with the Use of Numerical and Slater Type Atomic Orbitals: Application to Paramagnetic Defects.* Journal of Physical Chemistry A 112, 4521 (2008) (https://doi.org/10.1021/jp800494m).

[2] E.S. Kadantsev and T. Ziegler, *Implementation of a DFT Based Method for the Calculation of Zeeman g-tensor in Periodic Systems with the use of Numerical and Slater Type Atomic Orbitals.* Journal of Physical Chemistry A 113, 1327 (2009) (https://doi.org/10.1021/jp805466c).

Default value No

GUI name :A-tensor

Description Compute the hyperfine A-tensor.

Note: Unrestricted calculation is required.

Two methods are used for A-tensor calculation:

- Method 1: involves the gradient of the spin-polarized density and integration by parts. The isotropic component of the A-tensor obtained through integration, in a "non-local fashion".

- Method 2: the A-tensor is computed from spin-polarized density and does not relies on the integration by parts. The isotropic component is obtained in a "local fashion" from the value of the spin-polarized density on the grid points near the nuclei.

The user should be aware that numerical integration in A- and g-tensor routines is carried out over the Wigner-Seitz (WS) cell, and, therefore, to obtain a meaningful result, the defect in question should lie at or very close to the WS cell origin. This might require, on the user's part, some modification of the input geometry.

It also might happen that the size of the WS cell is not large enough for the adequate description of the paramagnetic defect in question. In this case, Method 1 will fails, since it relies on the integration by parts and assumes that the spin-polarized density is localized inside the WS cell. For the same reason, we recommend that the user removes diffuse basis set functions that describe the defect subsystem.

Finally, we note that the final result for A-tensor as presented by BAND is not scaled by the nuclear spin (as it is done in ADF) and the user is responsible for making necessary adjustments.

g-tensor

The calculation of the Zeeman g-tensor is invoked within the ESR block:

```
ESR
   Enabled Yes/No
End
```

ESR

Type Block

Description Zeeman g-tensor. The Zeeman g-tensor is implemented using two-component approach of Van Lenthe and co-workers in which the g-tensor is computed from a pair of spinors related to each other by time-reversal symmetry. Note: the following options are necessary for ESR: 'Relativistic zora spin' and 'Kspace 1'

Enabled

Type Bool

Default value No

GUI name ESR: g-tensor

Description Compute Zeeman g-tensor.

The Zeeman g-tensor is implemented using two-component approach of Van Lenthe and co-workers in which the g-tensor is computed from a pair of spinors related to each other by time-reversal symmetry.

Note: the following options are necessary for ESR: 'Relativistic zora spin' and 'Kspace 1'

(Γ-only calculation). The g-tensor is then computed from the HOMO spinor at the Γ point. In the output, the user can find two-contributions to the g-tensor: one that stems from the K_σ operator and a second one, that stems from the

orbital angular momentum. By default, GIAO and spin-Zeeman corrections are **not** included. From our experience, these corrections are quite small.

5.5 Nuclear Quadrupole Interaction (EFG)

```
EFG
    Enabled Yes/No
End
```

EFG

> **Type** Block
>
> **Description** The electronic charge density causes an electric field, and the gradient of this field couples with the nuclear quadrupole moment, that some (non-spherical) nuclei have and can be measured by several spectroscopic techniques. The EFG tensor is the second derivative of the Coulomb potential at the nuclei. For each atom it is a 3x3 symmetric and traceless matrix. Diagonalization of this matrix gives three eigenvalues, which are usually ordered by their decreasing absolute size and denoted as V_{xx}, V_{yy}, V_{zz}. The result is summarized by the largest eigenvalue and the asymmetry parameter.

> **Enabled**
>
> > **Type** Bool
> >
> > **Default value** No
> >
> > **GUI name** EFG (electric field gradient): Calculate
> >
> > **Description** Compute the EFG tensor (for nuclear quadrupole interaction).

This option honors the `SelectedAtoms` key, in which case only the EFG will be calculated for the selected atoms.

5.6 NMR

> **Warning:** The calculations of NMR shielding with BAND has not been thoroughly tested and the results might be unreliable. One should be extra careful when running NMR calculation, and validate the results by using different super-cells and different technical parameters.

With the NMR option the *shielding tensor* is calculated. There are two methods implemented: the super cell method and the single-dipole method.

I) The super cell method is according to the implementation by Skachkov *et al.*[1] The symmetry will be automatically disabled. The unit cell should not be chosen too small.

II) The other method is the single-dipole method. In principle one can now use the primitive cell[2]. In practice also this method needs to be converged with super cell size. However, depending on the system the required super cell may be much smaller. At a given super cell size this method is more expensive than the super cell method.

---

[1] D. Skachkov, M. Krykunov, E. Kadantsev, and T. Ziegler, *The Calculation of NMR Chemical Shifts in Periodic Systems Based on Gauge Including Atomic Orbitals and Density Functional Theory.* Journal of Chemical Theory and Computation 6, 1650 (2010) (https://doi.org/10.1021/ct100046a).

[2] D. Skachkov, M. Krykunov, and T. Ziegler, *An improved scheme for the calculation of NMR chemical shifts in periodic systems based on gauge including atomic orbitals and density functional theory*, Canadian Journal of Chemistry 89, 1150 (2011) (https://doi.org/10.1139/V11-050).

```
NMR
   Enabled Yes/No
   SuperCell Yes/No
End
```

NMR

> **Type** Block
>
> **Description** Options for the calculations of the NMR shielding tensor.

Enabled

> **Type** Bool
>
> **Default value** No
>
> **Description** Compute NMR shielding.

SuperCell

> **Type** Bool
>
> **Default value** Yes
>
> **Description** This is the switch between the two methods, either the super cell (true), or the single-dipole method (false)

This option honors the `SelectedAtoms` key, in which case only the NMR properties will be calculated for the selected atoms only.

5.7 Effective Mass

```
EffectiveMass
   Enabled Yes/No
   KPointCoord float_list
   NumAbove integer
   NumBelow integer
   StepSize float
End
```

EffectiveMass

> **Type** Block
>
> **Description** In a semi-conductor, the mobility of electrons and holes is related to the curvature of the bands at the top of the valence band and the bottom of the conduction band.
>
> With the effective mass option, this curvature is obtained by numerical differentiation.
>
> The estimation is done with the specified step size, and twice the specified step size, and both results are printed to give a hint on the accuracy. The easiest way to use this key is to enabled it without specifying any extra options.

Enabled

> **Type** Bool
>
> **Default value** No
>
> **GUI name** Effective mass

> **Description** Compute the EffectiveMass.

KPointCoord

> **Type** Float List
>
> **Unit** 1/Bohr
>
> **Recurring** True
>
> **GUI name** At K-point
>
> **Description** Coordinate of the k-points for which you would like to compute the effective mass.

NumAbove

> **Type** Integer
>
> **Default value** 1
>
> **GUI name** Include N bands above
>
> **Description** Number of bands to take into account above the Fermi level.

NumBelow

> **Type** Integer
>
> **Default value** 1
>
> **GUI name** Include N bands below
>
> **Description** Number of bands to take into account below the Fermi level.

StepSize

> **Type** Float
>
> **Default value** 0.001
>
> **Description** Size of the step taken in reciprocal space to perform the numerical differentiation

5.8 Properties at Nuclei

PropertiesAtNuclei (block-type) A number of properties can be obtained near the nucleus. An average is taken over a tiny sphere around the nucleus. The following properties are available.

```
PropertiesAtNuclei
  vxc[rho(fit)]
  rho(fit)
  rho(scf)
  v(coulomb/scf)
  rho(deformation/fit)
  rho(deformation/scf)
End
```

The electron density, `rho(scf)`, is physically the most relevant one.

5.9 X-Ray Form Factors

X-ray structure factors (Fourier analysis of the charge density) are computed by default after termination of the SCF procedure.

Form factors options:

```
FormFactors integer
```

FormFactors

> **Type** Integer
>
> **Default value** 2
>
> **Description** Number of stars of K-vectors for which the form factors are computed

5.10 Dipole moment and Berry Phase

By default, Band computes (and prints to the output) only the components of the dipole moment orthogonal to the periodic direction(s).

Since the position operator is ill-defined in periodic systems, computing the longitudinal components of the dipole moment (i.e. the components along periodic directions) is not completely trivial. To obtain the longitudinal components of the dipole moment, you can perform a Berry Phase calculation:

```
BerryPhase Yes/No
```

BerryPhase

> **Type** Bool
>
> **Default value** No
>
> **Description** Boolean that determines whether the dipole as determined through the Berry phase approach should be calculated.

In the graphical user interface (AMSinput) you can find the Berry Phase checkbox in the **Details → Expert BAND** panel.

In a Berry phase calculation, the dipole moment of a unit cell is calculated with the help of the geometric phase within the unit cell. The theoretical framework of the calculations originates from the *'Modern theory of polarization'* that was come up with in the early 1990s by King-Smith, Vanderbilt and Resta.[1][2] The implementation in BAND is a generalization of the one-dimensional Berry phase approach for quantum chemistry codes with local basis sets devised by Kudin and Car.[3]

> **Warning:** The Berry phase implementation in BAND has been thoroughly for 1D systems. Nonetheless, the implementation seems to break down for 2D and 3D systems, thus requiring careful testing and validation of the calculations for such systems.

---

[1] R. King-Smith, D. Vanderbilt, *Theory of polarization of crystalline solids.* Physical Review B 47, 1651 (1993) (https://doi.org/10.1103/PhysRevB.47.1651).
[2] R. Resta, *Macroscopic polarization in crystalline dielectrics: the geometric phase approach.* Reviews of Modern Physics 66, 899 (1994) (https://doi.org/10.1103/RevModPhys.66.899).
[3] K. Kuding, R. Car, *Berry phase approach to longitudinal dipole moments of infinite chains in electronic-structure methods with local basis sets* Journal of Chemical Physics 126, 234101 (2007) (https://doi.org/10.1063/1.2743018).

> **Warning:**
>
> - Berry phase calculations require orthorhombic unit cells, differently shaped unit cells are not currently supported.
>
> - For Berry Phase calculations you should use an all *electron basis set* (page 46) (i.e. Set the `core` to `none`)
>
> - Using a good k-space sampling is recommended for Berry Phase calculations

An option that can be useful when validating the Berry Phase calculation is `ShiftCoordinates` in the AMS System block:

```
System header
   ShiftCoordinates float_list
End
```

System

    ShiftCoordinates

        Type Float List

        Unit Bohr

        Description Translate the atoms by the specified shift (three numbers).

5.11 GW

5.11.1 General

This page describes the basic procedure, usage and scope of a GW calculation. Technical details of the algorithm can be tweaked in the *MBPT input block* (page 86).

See also:

Examples GW (page 264)

The GW method is a relatively accurate method to obtain information about so-called charged excitations, or single-particle excitations. We refer to them as Quasiparticle energies. These are especially important to interpret and predict the outcome of direct and inverse photo-emission spectroscopy and can be used to obtain e.g. very accurate ionization potentials and electron affinities which gives access to the so-called fundamental gap (not to be confused with the optical gap).

GW can be used icw scalar relativistic effects within the `ZORA` formalism.

In practice, fully self-consistent GW is rarely used for molecular systems. Instead, perturbative approximations, so called quasiparticle GW methods are used since they are cheaper and also more accurate than fully self-consistent GW. The most popular approach is G_0W_0[1], in which quasiparticle energies are obtained as a one-shot perturbative correction to KS eigenvalues. A downside of this approach is the rather pronounced starting-point dependence. This can be overcome to a large extent in eigenvalue-only self-consistent GW (evGW), in which the quasiparticle energies (but not the density) are iteratively updated until self-consistency is reached. In quasiparticle self-consistent GW, also the density is updated in each iteration, so that the results become completely starting point independent. The partially self-consistent GW variants usually converge within 6-8 iterations which make these approaches a factor of 6 to 8 more expensive than G_0W_0.

---

[1] Arno Förster, Lucas Visscher, *Low-order scaling G0W0 by pair atomic density fitting*, Journal of Chemical Theory and Computation 16 (12), 7381–7399 (2020) (https://doi.org/10.1021/acs.jctc.0c00693)

A GW calculation as implemented in BAND proceeds in five steps as has been described in detail in a series of papers[?56]. The technique is also known as the as GW space-time method. Our implementation is closely related to the scheme outlined in[4].

- A DFT single-point calculation is performed. This can be an LDA, GGA or hybrid calculation. At the moment, BAND does not support the use of XCfun, but libXC is supported. Valid choices could be LDA, PBE, BLYP, PBE0, BHandHLYP and many more. The default is LDA. As usual, the functional to be used during the SCF is requested in the *XC input block* (page 13) block. The following requests a G_0W_0 calculation with default settings using a PBE reference:

```
XC
    GGA PBE
END

GW
End
```

Hybrid starting points can be requested with the `LibXC` key.

- From the KS orbitals and orbital energies, a Green's function (G) is evaluated and from the Green's function the so-called independent-particle polarizability is calculated. This is done in imaginary time.

- The polarizability is Fourier transformed to the imaginary frequency axis where the screened Coulomb potential (W) is evaluated using the Coulomb potential and the polarizability.

- The screened Coulomb potential is Fourier transformed to imaginary time. Here, the self-energy is calculated using G and W (that why it is called GW) which gives access to spectroscopic properties.

- The self-energy is transformed to the molecular orbital basis from where it is Fourier transformed to the imaginary frequency axis from where it is analytically continued to the complex plane. Along the real frequency axis, the quasiparticle energies are evaluated.

- In case of evGW ($evGW_0$), the input KS eigenvalues are replaced by the quasiparticle energies from the previous iteration and the scheme is iterated until self-consistency in the quasiparticle energies is reached.

- In case of qsGW ($qsGW_0$), A non-local, hermitian, and static exchange-correlation potential is constructed from the self-energy. This exchange-correlation potential replaces the KS exchange-correlation potential. Diagonalization gives a new set of single-particle orbitals and quasiparticle energies. The procedure is repeated until self-consistency is reached.

- By default, the DIIS algorithm is used to accelerate and stabilize convergence of the self-consistent GW schemes. A linear-mixing scheme can also be used.

The GW space-time method has the distinct advantage that it can be very fast, while a full frequency, conventional GW calculation scales to the 6th power of the system size and is prohibitive for systems larger than a few tens of atoms. BAND used advanced density fitting options to accelerate the space-time method further and in practice nearly quadratic scaling can be reached. This enables the routine application of the method to systems of several hundreds of atoms. A G_0W_0 calculation (without the preceding SCF) is usually not much slower than a hybrid calculation. The downside of the approach is that the analytical continuation technique produces large errors (up to several eV) for core states which are in example important in X-ray spectroscopy. Thus, the GW implementation in BAND should only be used to predict quasiparticle energies for states in the valence-region. In fact, we have only tested it for HOMO and LUMO states (which are arguably most important)

The states of interest can be requested in the GW block

```
GW
  nStates 5
End
```

is the default and calculates 5 occupied and five unoccupied states.

```
GW
  nStates 1
End
```

calculates the HOMO and LUMO quasiparticle energy only.

5.11.2 Levels of self-consistency

Eigenvalue-only self-consistent GW

An evGW calculation is requested by

```
GW
  SelfConsistency evGW
End
```

One can also only iterate G by keep W fixed which reduces the cost of each iteration by roughly 50 %. This is requested by

```
GW
  SelfConsistency evGW0
End
```

On the other hand, much of the starting point dependence of the G_0W_0 method remains in the $evGW_0$ method and it is generally not recommended.

quasiparticle self-consistent GW

An qsGW calculation is requested by

```
GW
  SelfConsistency qsGW
End
```

One can also only iterate G by keep W fixed which reduces the cost of each iteration by roughly 50 %. This is requested by

```
GW
  SelfConsistency qsGW0
End
```

On the other hand, much of the starting point dependence of the G_0W_0 method remains in the $qsGW_0$ method and it is generally not recommended.

More options:

QPHamiltonian In quasiparticle self-consistent GW, the frequency-dependent self-energy is mapped to a static exchange-correlation in each iteration. The mapping is not unique and different schemes have been suggested. They differ in the way the frequency dependence of the self-energy is treated. In BAND, three variants can be

used. KSF1 and KSF2 are from the paper by Kotani et al.[7]. KSF1 refers to eq. 10 therein and is most commonly implemented, KSF2 refers to eq. 11 therein. KSF2 is the default in BAND since it is numerically more stable. The variant denoted as Kutepov has been suggested bu Kutepov et al.[8] and uses a first-order expansion around the chemical potential.

FixedGrids Per default, the imaginary frequency and imaginary time grids used in the GW calculation are updated in each iteration in a qsGW calculation since this is necessary to make the results strictly starting point dependent. This can also be turned off, and fixed grids are used throughout. This might be helpful in case of convergence problems.

Convergence

The self-consistency can be controlled by a few parameters: For example

```
GW
  Converge HOMO=5e-3
End
```

requests that the evGW(0) calculation is considered converged if the difference between the HOMO quasiparticle energies of 2 consecutive iterations does not change by more than 5 meV. The default is 1 meV which is in practice usually a little too tight. We recommend to adjust this parameter according to your requirements, for example the experimental resolution you would like to match.

For qsGW (qsGW$_0$), the change in the norm of the density matrix is used as an additional criterion to control convergence. In evGW (evGW$_0$) it is ignored.

```
GW
  Converge Density=1e-07
End
```

is the default. For very large systems and when QZ basis sets are used, it is recommended to decrease that value, for example to

```
GW
  Converge Density=1e-08
End
```

```
GW
  linearmixing 0.2
End
```

turns of DIIS and request to use linear mixing instead with a mixing parameter of 0.2. This can be useful if for some reason, convergence using DIIS cannot be achieved. However, it is usually better to adjust the number of vectors in the DIIS expansion. This is achieved by (for example)

```
GW
  DIIS 5
End
```

The default are 10 expansion vectors. In case of difficulties converging

5.11.3 Second-order self-energy

Starting from ADF2BAND, it is possible to go beyond the GW approximation for the self-energy (expansion in screened interaction to first order) and also take into account the next term (expansion in the screened interaction to second order). The algorithm has been described in this paper. ..[10]

- This can be used with all variants of self-consistency.

- The second-order self-energy is always applied as a perturbative correction of the GW quasiparticle energies, using a statically screened interaction W. More precisely,

$$\Sigma^{GW} = G(\omega) * W(\omega)$$

$$\Sigma^{GW+G3W2} = G(\omega) * W(\omega) + G(\omega) * W(\omega = 0) * G(\omega) * G(\omega) * W(\omega = 0)$$

- The second-order self-energy is activated by typing

```
GW
   selfenergy G3W2
End
```

- It has been shown that the second-order correction is especially accurate for electron affinities and HOMO-LUMO gaps.[?] Since it effectively scales as the fourth power of the system size, it should not be used for systems much larger than 50 atoms.

5.11.4 Recommendations

Basis sets

The recommended numerical settings depend strongly on the basis set. The recommended basis set depends on system size and the property of interest. The following are recommendations which should be seen as guidelines and not as definite. We recommend to always verify the basis set convergence of for the property of interest. Details about basis set convergence can be found in this paper[?]

Basis sets

All-electron: All-electron calculations are always recommended.
Basis set size: Larger basis sets are needed to achieve the same accuracy as in a DFT calculation
Augmented basis sets: Should only be used if absolutely necessary. They are however often necessary for an accurate description of the electron affinity for molecules with LUMO above the vacuum level.

Ionization Potentials: TZ2P or larger
Electron affinities, bound LUMO: Corr/TZ3P or larger
Electron affinities, unbound LUMO: AUG/ATZ2P or larger
Fundamental Gaps: Triple-zeta quality basis sets are typically sufficient.

The GW-BSE excitation energies and the screened Coulomb interaction do only depend on the QP gaps and not on their absolute values. Therefore, triple-zeta quality basis sets are typically sufficient.

---

[10] A. Förster, L. Visscher, *EGW100: A Slater-Type Orbital Perspective*, Journal of Chemical Theory and Computation 17(8), 5080-5097 (2021) (https://doi.org/10.1021/acs.jctc.1c00308)

For **highly accurate results** we recommend to perform an extrapolation to the complete basis set limit: For this, perform 2 calculations using the Corr/TZ3P and Corr/QZ6P. The basis set limit is then calculated according to

$$\epsilon_n^{CBS} = \epsilon_n^{QZ} - \frac{1}{N_{bas}^{QZ}} \frac{\epsilon_n^{QZ} - \epsilon_n^{TZ}}{\frac{1}{N_{bas}^{QZ}} - \frac{1}{N_{bas}^{TZ}}}$$

The values for N_{bas}^{TZ} and N_{bas}^{QZ} can be found in the BAND.rkf file in the `GW` section under the entry `nBas`. Additional explanations can be found in the references[3] and[?]

Numerical aspects

- According to the choice of basis set, the recommended numerical settings can differ. For a discussion, see the *MBPT page* (page 86).

- qsGW has the highest requirements on the numerical parameters than evGW and G_0W_0. Usually, it is necessary to use a larger value in the `Dependency` key, see the *MBPT page* (page 86). Note that starting from AMS2022 BAND will use a `Dependency bas=5e-3` and `RIHartreeFock DependencyThreshold=5e-3` in case of (any variant of) GW. One can override these values in the input.

- The implemented GW algorithm is very sensitive to numerical noise and depending on the numerical settings and/or the underlying exchange-correlation functional, (occupied) quasiparticle energies from partially self-consistent GW calculations performed on different hardware can differ by a few meV. The discrepancies are generally more pronounced for core states for which the analytical continuation technique is rather inaccurate.

- In our experience, these differences only occur with large basis sets (QZ4P or larger) and when Minnesota functionals (we tested M06, M06-2X and M06-HF) are used to calculate the KS reference. When the DIIS algorithm is used to converge the quasiparticle energies, the number of iterations needed for convergence can then differ as well.

- For optimal accuracy, full cores should be used. Note, that frozen cores do not require in large computational savings for GW calculations.

Choosing the KS reference

- As for ground-state properties, it is far from trivial to recommend a universal functional. However, for G_0W_0 calculations, a few general guidelines can be offered. A good discussion is found in[2]. It should be noted, that GGA functional should not be used, even though a PBE starting point is a popular choice. We rather recommend to use a hybrid functional. The relevant parameter in the choice of the hybrid is usually the fraction of exact exchange. In our experience, PBE0 with 40-50 % exact exchange is a good choice. You might also use a range-separated hybrid via LibXC, for example LRC-wPBEH.

- If in doubt, one of the partially self-consistent schemes should be used. evGW is almost starting point independent and qsGW is completely starting point independent. Therefore, for qsGW, it is in principle irrelevant what starting point is chosen. Convergence properties can in principle be affected, although the number of iterations until convergence is reached is also more or less independent of the starting point[?]. Also for evGW, starting from a hybrid functional or a range-separated functional usually results in the highest accuracy.

   SelfConsistency

> **Type** Multiple Choice
>
> **Default value** G0W0

Options [G0W0, EVGW0, EVGW, QSGW0, QSGW]

Description Sets the level of self-consistency in a GW calculation.

G0W0 calculates a one-shot, perturbative correction to the KS eigenvalues.

In evGW and evGW0, the quasi-particle energies are updated until self-consistency is reached.

evGW0 requests that the Green's function is evaluated self-consistently but not the screened interaction.

In qsGW, the density is updated as well, however, the self-energy is mapped to a static effective potential and the Dyson equation is solved by diagonalization instead of inversion. The results of a qsGW are independent of the choice of the underlying exchange-correlation functional and are usually the most accurate ones.

The same is done in qsGW0, but the screened interaction is not updated.

QPHamiltonian

Type Multiple Choice

Default value KSF2

Options [KSF1, KSF2, SRG, LQSGW]

Description The quasi-particle Hamiltonian can be constructed in different ways.

KSF1 refers to the original construction by Kotani, Van Schilfgaarde anf Faleev (KSF) which is also implemented in TURBOMOLE.

KSF2 refers to an alternative construction by KSF.

KSF1 is not recommended since it is numerically less stable than KSF2. The results are typically very similar.

The QP energies at which the matrix elements are evaluated can be tweaked further, see the two subsequent keys: However, KSF2 is recommended since it typically leads to QP energies with the best agreement with experiment.

Ignored when not a quasi-particle self-consistent GW calculation is performed

nIterations

Type Integer List

Default value [10]

GUI name Number of iterations

Description The maximum number of iterations within the (partially or fully) self-consistent GW calculation has to converge.

Ignored when Formalism is set to G0W0

Converge

Type Block

Description Sets convergence criteria for the GW calculation in self-consistent case

Density

Type Float List

Default value [1e-08, 1e-05]

Description First Criterion for self-consistency procedure to terminate.

Criterion is the trace of the density matrix. Ignored in non-selfconsistent Calculation and in eigenvalue self-consistent GW

It is possible to run a qsGW calculation with an inner SCF loop which updates the static part of the elf-energy only. This can be useful to accelerate the convergence in case linear mixing is used. It is not recommended to use linear mixing, so it is also not recommened to use that inner loop as well. The second number in this list specifies the convergence criterion for the inner SCF loop.

HOMO

Type Float

Default value 0.003

Unit eV

GUI name HOMO energy convergence

Description Criterion for self-consistency procedure to terminate.

The self-consistent GW calculation terminates, when the difference between the HOMO QP energies between 2 consecutive iterations is below this number.

The LUMO energy converged faster than the HOMO energy so when the HOMO energy is converged according to this criterion, the LUMO energy will be converged as well.

In non-selfconsistent Calculation, this criterion is ignored.

FixedGrids

Type Bool

Default value No

Description In a self-consistent GW calculation, do not recalculate Grids. Can be useful in case of convergence problems. Only relevant for qsGW and qsGW0. In case of evGW and evGW0, the grids are always kept fixed.

preconditionQSGW

Type Bool

Default value No

Description If true, the QSGW equations are solved but prior to each diagonalization, i.e. a G0W0 calculation is performed to find the optimal QP energies at which to analytically continue the self-energy.

This is in principle a more consistent construction than KSF1 or KSF2 since the diagonal elements are consistent with G0W0.

In KSF1 and KSF2, the diagonal elements are evaluated at the QP energies from the previous iteration which is equivalent to a zeroth-order Taylor expansion of the diaognal elements around the previous QP energies.Enabling this option typically leads to slightly lower QP energies.

OffDiagonalEFermi

Type Bool

Default value No

Description Analytically continue the off-diagonal elements of the KSF2 qsGW Hamiltonian at the Fermi-energy instead of omega=0. Typically leads to slightly lower QP energies, i.e. higher ionization potentials. The HOMO-LUMO gaps are typically not affected.

LinearMixing

   Type Float List

   Description Requests to use linear mixing instead of DIIS and sets the mixing parameter for linear mixing of Green's function in case of self-consistency.

   It is ignored in non-selfconsistent calculation and overwritten by DIIS when DIIS is also present.

AdaptiveMixing

   Type Float List

   Description Requests to use adaptive mixing instead of DIIS and sets the staring mixing parameter for mixing of Green's function in case of self-consistency.

   Adapative mixing is recommenened in case a qsGW calculation does not converge with DIIS.

   It is ignored in non-selfconsistent calculation and overwritten by DIIS when DIIS is also present.

DIIS

   Type Integer

   Default value 10

   Description Requests to use DIIS. This is the Default. Number of expansion coefficients can be requested as well. Ignored in non-selfconsistent calculation

LinearizeQPequations

   Type Bool

   Default value No

   Description Instead of solving the non-linear QP equations in a G0W0 (or evGW calculation) by bisection exacly, linearize them by first-order Taylor expansion.

   This is not recommended since it does not save computational time when used together with analytical continuation (as implemented in AMS). It might however be useful for benchmarking or for validating results.

   If the results os the linearization differ by a lot (for instance, more than 0.1 eV in frontier QP energies) from the non-linearized results, this might indicate that the GW calculation is not reliable.

ScissorShift

   Type Bool

   Default value No

   Description Only calculate the HOMO and LUMO QP energies and shift the remaining QP energies by the same amount.

   This is a rather crude approximaiton and not recommended.

   It might again be useful for benchmarking purposes.

ANALYSIS

6.1 Density of States (DOS)

```
DOS
   CalcDOS Yes/No
   CalcPDOS Yes/No
   CalcPopulationAnalysis Yes/No
   CompensateDeltaE Yes/No
   DeltaE float
   Energies integer
   File string
   IntegrateDeltaE Yes/No
   Max float
   Min float
   StoreCoopPerBasPair Yes/No
End
```

DOS

> **Type** Block
>
> **Description** Density-Of-States (DOS) options

CalcDOS

> **Type** Bool
>
> **Default value** Yes
>
> **GUI name** Calculate DOS
>
> **Description** Whether or not to calculate the density of states.

CalcPDOS

> **Type** Bool
>
> **Default value** No
>
> **GUI name** Calculate PDOS
>
> **Description** Whether or not to calculate the partial DOS (projections on basis functions). This can be significantly more expensive than calculating the total DOS

CalcPopulationAnalysis

> **Type** Bool
>
> **Default value** Yes

GUI name Calculate Mulliken charges

Description Whether or not to calculate the population analysis. Population analysis can become very expensive when there are many symmetry operators, such as in a super cell.

CompensateDeltaE

Type Bool

Default value Yes

Description Only relevant when IntegrateDeltaE=yes. If set to true then after integrating each interval over DeltaE the result is divided by DeltaE, so that the unit is DOS.

DeltaE

Type Float

Default value 0.005

Unit Hartree

GUI name Delta E

Description Energy step for the DOS grid. Using a smaller value (e.g. half the default value) will result in a finer sampling of the DOS.

Energies

Type Integer

Description Number of equidistant energy-values for the DOS grid. This keyword is superseded by the 'DeltaE' keyword.

File

Type String

Description Write the DOS (plain text format) to the specified file instead of writing it to the standard output.

IntegrateDeltaE

Type Bool

Default value Yes

Description This subkey handles which algorithm is used to calculate the data-points in the plotted DOS. If true, the data-points represent an integral over the states in an energy interval. Here, the energy interval depends on the number of Energies and the user-defined upper and lower energy for the calculation of the DOS. The result has as unit [number of states / (energy interval * unit cell)]. If false, the data-points do represent the number of states for a specific energy and the resulting plot is equal to the DOS per unit cell (unit: [1/energy]). Since the resulting plot can be a wild function and one might miss features of the DOS due to the step length between the energies, the default is set to the integration algorithm.

Max

Type Float

Unit Hartree

Description User defined upper bound energy (with respect to the Fermi energy)

Min

Type Float

> **Unit** Hartree
>
> **Description** User defined lower bound energy (with respect to the Fermi energy)

StoreCoopPerBasPair

> **Type** Bool
>
> **Default value** No
>
> **GUI name** Calculate COOP
>
> **Description** Calculate the COOP (crystal orbital overlap population).

An example input:

```
DOS
   Enabled      True
   Energies     500
   Min          -0.35
   Max          1.05
   File         plotfile
End
```

According to this example, DOS values will be generated in an equidistant mesh of 500 energy values, ranging from 0.35 a.u. below the Fermi level to 1.05 a.u. above it. All information will be written to a file plotfile. The information on the plot file is a long list of pairs of values (energy and DOS), with some informative text-headers and general information. DOS values are generated for the total DOS and optionally also for some partial DOS (see the keys *GrossPopulations* (page 123) and *OverlapPopulations* (page 124)).

A common problem is that of missing DOS: an energy interval with bands but no DOS. This is caused by an insufficient k-space sampling. Try to *Restart the DOS* (page 162) with a better k-grid.

In the **DOS** and **Band Structure GUI modules**, it is possible to visualize partial density of states (**p-DOS**). The partial contributions are obtained from the total DOS by following the **Mulliken population analysis** partitioning prescription (see wikipedia (https://en.wikipedia.org/wiki/Mulliken_population_analysis)).

Tip: The tutorial Calculation of Band Structure and COOP of CsPbBr3 with BAND contains some advanced usage of the **DOS** and **BAND Structure GUI modules**.

6.1.1 Gross populations

```
GrossPopulations # Non-standard block. See details.
   ...
End
```

GrossPopulations

> **Type** Non-standard block
>
> **Description** Partial DOS (pDOS) are generated for the gross populations listed under this key. See example.

Syntax:

```
GrossPopulations
   {iat lq}
   {FragFun jat ifun}
```

```
   {Frag kat}
   {Sum
    ...
    EndSum}
End
```

iat pDOS is generated for atom *lq*.

FragFun pDOS is generated for atom *jat* with all real spherical harmonics belonging to *l*-value *ifun*.

Frag pDOS of the functions belonging to atom *kat* will be calculated.

Sum sum all pDOS, specified in this block.

Example:

```
GrossPopulations
   FragFun 1 2:: Second function of first atom
   Frag 2 :: Sum of all functions from second atom
   SUM:: sum following PDOSes
      Frag 1::Atom nr.1
      FragFun 2 1::First function of second atom
      5 1:: All pfunctions of fifth atom
   EndSum
End
```

6.1.2 Overlap populations

```
OverlapPopulations # Non-standard block. See details.
   ...
End
```

OverlapPopulations

> **Type** Non-standard block
>
> **Description** Overlap population weighted DOS (OPWDOS), also known as the crystal orbital overlap population (COOP).

Overlap population weighted DOS are generated for the overlap populations listed:

```
OVERLAPPOPULATIONS
   Left
      { iat lq }
      { FragFun jat ifun }
      { Frag kat }
   Right
      ...
End
```

You can use this to get the OPWDOS of two functions, or, if you like, one bunch of functions with another bunch of functions. The key-block should consist of left-right pairs. After a line with left you enter lines that specify one or more functions (according to *GrossPopulations* (page 123)), followed by a similar structure beginning with right, which will produce the OPWDOS of the left functions with the right functions.

Example:

```
OVERLAPPOPULATIONS
   LEFT::First OPWDOS
      Frag 1
   RIGHT
      Frag 2
   LEFT:: Next OPWDOS
      FragFun 1 1
   RIGHT
      2 1
      FragFun 3 5
End
```

6.2 Band Structure

BAND can calculate the band structure for the standard k-path in the Brillouin zone[1] and saves the corresponding data to the binary file RUNKF.

The band structure is best examined with the GUI module **BandStructure** see:

- Advanced BAND tutorial: Calculation of Band Structure and COOP of CsPbBr3 with BAND

```
BandStructure
   Enabled Yes/No
   Automatic Yes/No

Information on the k-path used for band structure plotting (including the fractional coordinates of high-symmetry k-points) can be found in the section `KPath` of the output file.

6.2.1 User-defined path in the Brillouin zone

If `BZStruct%Automatic` is `False`, BAND will compute the band structure for the user-defined path in the `BZPath` block.

```
BZPath
    path # Non-standard block. See details.
       ...
    End
End
```

BZPath

> **Type** Block
>
> **Description** Definition of the user-defined path in the Brillouin zone for band structure plotting.

> **path**

>> **Type** Non-standard block
>>
>> **Recurring** True
>>
>> **Description** Definition of the k-points in a path. The vertices of your path should be defined in fractional coordinates (wrt the reciprocal lattice vectors)

You should define the vertices of your path in fractional coordinates (wrt the reciprocal lattice vectors) in the `Path` sub-block. If you want to make a *jump* in your path, you need to specify a new `Path` sub-block.

In the following example we define the path `Gamma-X-W-K|U-X` for a FCC lattice:

```
BZPath
   Path
      0.000    0.000    0.000
      0.500    0.000    0.500
      0.500    0.250    0.750
      0.375    0.375    0.750
   End
   Path
      0.625    0.250    0.625
      0.500    0.000    0.500
   End
End
```

6.2.2 Definition of the Fat Bands

The *fat bands* (page 125) $F_{i,n,\sigma,\vec{k}}$ are the periodic equivalent of the Mulliken population. They are defined as:

$$F_{i,n,\sigma,\vec{k}} = \sum_j C_{i,n,\sigma,\vec{k}} C_{j,n,\sigma,\vec{k}} S_{i,j,\vec{k}}$$

where $C_{i,n,\sigma,\vec{k}}$ and $S_{i,j,\vec{k}}$ are the orbital coefficients and the overlap matrix elements respectively. The indices i and j denote basis functions, n is the band index, σ is the spin index and $\vec{k}$ is a reciprocal vector in the Brillouin zone.

6.2.3 Band Gap

The band gap (if any) is printed in the output. Here is an example for the NaCl crystal:

```
---------------------------------------
Band gap information
---------------------------------------
Number of valence electrons                    16
Valence Band index                              8
Top of valence Band (a.u.)                 -0.192
Bottom of conduction Band (a.u.)           -0.039
Band gap (a.u.)                             0.153
Band gap (eV)                               4.173
Band gap (kcal)                            96.235
```

6.2.4 Calculation of the Fermi Surface

If the system has no band gap it is a metal, and that means that the Fermi surface is a complex shape in the Brillouin zone. As multiple bands may be crossing the fermi energy there may be multiple surfaces. In case of a spin unrestricted calculation both spins have a Fermi surface of their own. For 2D systems the "surface" consists of one or more lines. The result can be viewed with the GUI module AMSbands.

- Advanced BAND tutorial: Bands, dos and Fermi surface with BAND

```
FermiSurface

>   **Description** Improves the matching of the interpolated quadratic surface. For better results it
>   makes more sense to increaes KIntegForSymmetricKGrid.

6.3 Charges

6.3.1 Default Atomic Charge Analysis

By default BAND computes the following atomic charge analyses:

- **Hirshfeld Charges**[1][2]

- **Voronoi Deformation Charges** (VDD, Voronoi Deformation Density)

- **Mulliken Charges** (note: not calculated for *Spin-Orbit* (page 29) calculations)

- **CM5** (Charge Model 5)[3][4]

These atomic charges are printed to the output file and can be visualized using the AMSview GUI module.

A more detailed output of the atomic charges can be printed by specifying following print option (note: in Band 2017 and previous versions this detailed output was printed by default):

```
Print AtomicChargesDetails
```

6.3.2 Bader Analysis (AIM)

The QTAIM (Quantum Theory of Atoms in Molecules), also known as Bader Analysis can be enabled in the Grid-BasedAIM input block:

```
GridBasedAIM
   Enabled Yes/No
   Iterations integer
   SmallDensity float
   UseStartDensity Yes/No
End
```

GridBasedAIM

>   **Type** Block

>   **Description** Invoke the ultra fast grid based Bader analysis.

>   **Enabled**

>>   **Type** Bool

>>   **Default value** No

>>   **GUI name** Bader (AIM): Atomic properties

>> **Description** The distance between the initial trial points.

Note: The Bader (AIM) analysis is performed on the fitted density (see *ZlmFit* (page 65)). We advise to use a Good (or better) ZlmFit quality.

6.4 Fragments

A fragment feature is available albeit rather primitive. It allows for the analysis of the DOS in a fragment basis and for the calculation of the deformation density with respect to fragment densities. A typical application is the periodical adsorption of one or more molecules on a surface. For instance, consider periodic adsorption of hydrogen molecules over a surface. First you calculate the free molecule in the same orientation as when adsorbed to the substrate. Since you would like to use a molecular fragment, it makes sense to put the molecules far apart (large lattice spacing) and force dispersion to be neglected (KSPACE 1). To use the fragment in the next run you need to rename the result file ("rkf"), to something like "frag.rkf", see the example script discussed below or the *example* (page 265) covering this topic.

```
Fragment
   AtomMapping # Non-standard block. See details.
      ...
   End
   Filename string
   Labels # Non-standard block. See details.
      ...
   End
End
```

Fragment

>> **Type** Block

>> **Recurring** True

>> **Description** Defines a fragment. You can define several fragments for a calculation.

AtomMapping

>> **Type** Non-standard block

>> **Description** Format 'indexFragAt indexCurrentAt'. One has to associate the atoms of the fragment to the atoms of the current calculation. So, for each atom of the fragment the indexFragAt has to be associated uniquely to the indexCurrentAt for the current calculation.

> **Filename**
>
> > **Type** String
> >
> > **Description** Filename of the fragment. Absolute path or path relative to the executing directory.
>
> **Labels**
>
> > **Type** Non-standard block
> >
> > **Description** This gives the possibility to introduce labels for the fragment orbitals. See examples.

Example:

```
Fragment
  filename test.rkf
  AtomMapping
    1 3 !  atom 1 of this fragment is assigned to third atom
    2 4 !  atom 2 of this fragment is assigned to fourth atom
  End
  Labels
    Sigma
    Sigma*
    Pi_x
    Pi_y
    Pi_x*
    Pi_y*
  End
End
```

In this example the first six fragment orbitals will be labeled as stated in the body of this key. The remaining orbitals are labeled by the default labeling system (e.g. 1/FO/5, etc.). The labels are used in combination with options like `Print Eigens` and `Print OrbPop`. (See also `Print OrbLabels`). This key can be given once for each fragment.

Tip: Specifying:

```
Print Eigens
```

for a calculation produces output concerning the eigen states, thereby providing a means to identify the eigen states (e.g. to be sigma, pi, et cetera). So, one can label the orbitals of a fragment according to this information.

6.5 Energy Decomposition Analysis

In BAND there are two fragment-based energy decomposition methods available: the periodic energy decomposition analysis (PEDA)[1] and the periodic energy decomposition analysis combined with the natural orbitals of chemical valency method (PEDA-NOCV)[?].

---

[1] M. Raupach and R. Tonner, *A periodic energy decomposition analysis method for the investigation of chemical bonding in extended systems*, The Journal of Chemical Physics 142, 194105 (2015) (https://doi.org/10.1063/1.4919943).

6.5.1 Periodic Energy Decomposition Analysis (PEDA)

```
PEDA Yes/No
```

PEDA

> **Type** Bool
>
> **Default value** No
>
> **Description** If present in combination with the fragment block, the decomposition of the interaction
> energy between fragments is invoked.

If used in combination with the `fragment` keyblocks the decomposition of the interaction energy between fragments is invoked and the resulting energy terms (ΔE_{int}, ΔE_{disp}, ΔE_{Pauli}, ΔE_{elstat}, ΔE_{orb}) presented in the output file. (See the *example* (page 279) or the tutorial)

> **Attention:** In case of the error message "Fragments cannot be assigned by a simple translation!", BAND does only allow for fragments which can be transformed to the structure in the PEDA calculation by a simple translation. So, a rotation is not allowed.

6.5.2 Periodic Energy Decomposition Analysis and natural orbitals of chemical valency (PEDA-NOCV)

```
PEDANOCV (block-type)
```

If present in combination with the `fragment` keyblocks and the `PEDA` key the decomposition of the orbital relaxation term is performed. The binary result file will contain the information to *plot NOCV Orbitals and NOCV deformation densities* (page 159).

See also:

- *example* (page 282)

- tutorial

- advanced tutorial

```
PEDANOCV
   EigvalThresh float
   Enabled Yes/No
End
```

PEDANOCV

> **Type** Block
>
> **Description** Options for the decomposition of the orbital relaxation (pEDA).

EigvalThresh

> **Type** Float
>
> **Default value** 0.001
>
> **GUI name** Use NOCVs with ev larger than

Description The threshold controls that for all NOCV deformation densities with NOCV eigenvalues larger than EigvalThresh the energy contribution will be calculated and the respective pEDA-NOCV results will be printed in the output

Enabled

Type Bool

Default value No

GUI name Perform PEDA-NOCV analysis

Description If true in combination with the fragment blocks and the pEDA key, the decomposition of the orbital relaxation term is performed.

6.6 Local Density of States (STM)

In the **VIEW GUI module**, you can visualize the local density of states, see also the *LDOS (STM)* (page 160) key.

6.7 3D field visualization with BAND

With AMSview you can visualize three-dimensional fields from the results of a BAND Calculation (**runkf** file).

Following is a list of relevant fields, with a short explanation and illustrative pictures (from a simple non-periodic H_2 calculation). All fields are in atomic units (a.u.) (https://en.wikipedia.org/wiki/Atomic_units).

Total_Density (rho) The electronic density $\rho(r)$. The integral of the electronic density over the whole space (or, for periodic systems, over the unit cell) equals the total number of electrons (valence + core).
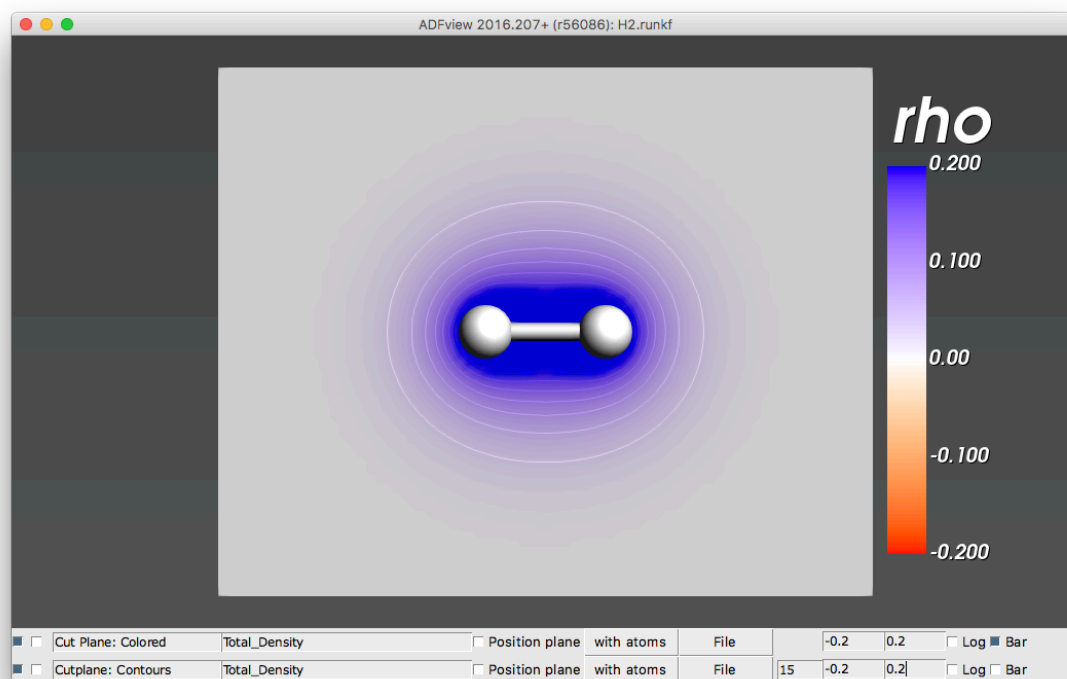

Deformation density (rho(deformation)) The deformation density is the difference between total density $\rho(r)$ and reference density $\rho_{\text{reference}}(r)$

$$\rho_{\text{deformation}}(r) = \rho(r) - \rho_{\text{reference}}(r)$$

The reference density $\rho_{\text{reference}}(r)$ is defined as the sum of densities of spherical spin-unrestricted isolated atoms.

The deformation density is electrically neutral, i.e. its integral over the whole space (or, for periodic systems, over the unit cell) is zero. Positive values of deformation density indicate density accumulation wrt isolated atoms; negative values represent density depletion. In our H_2 example, the deformation density shows how there is electron accumulation in the bonding region between the two hydrogen atoms.
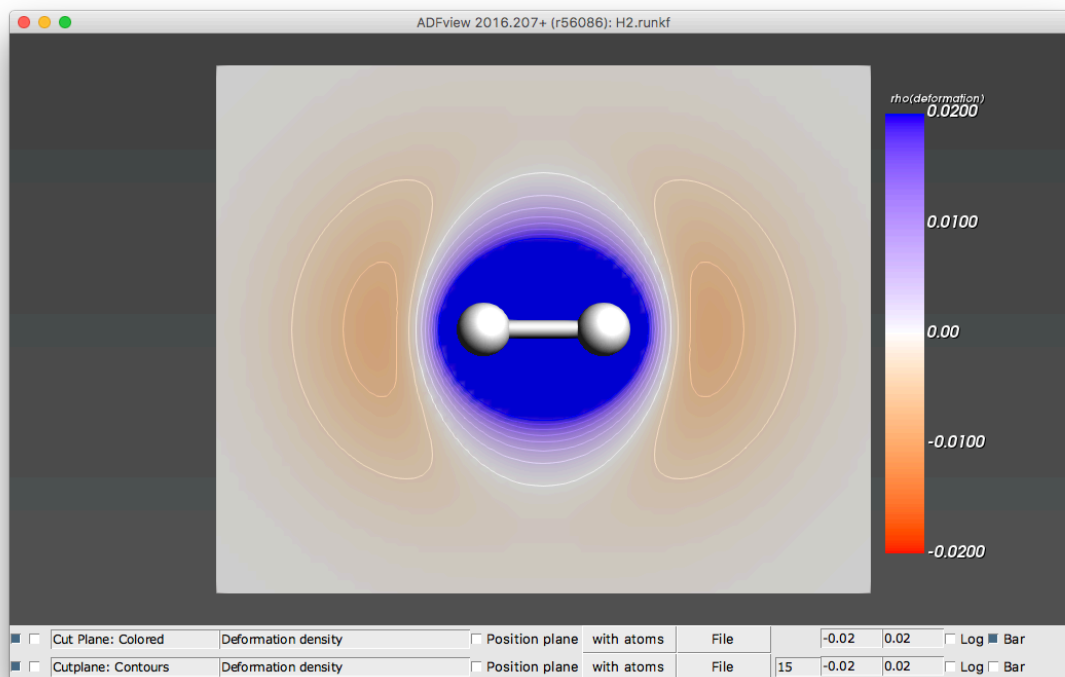

SCF_CoulombPot (v(coulomb)) The total Coulomb potential (nuclear + electronic potentials). BANDs convention for the Coulomb potential: the potential of positive charges (like nuclei) is **negative**, while the potential of negative charges (like electrons) is **positive**. In our example, the nuclear potential (negative) is larger than the electronic potential (positive) in the region of space near the H_2 molecule.
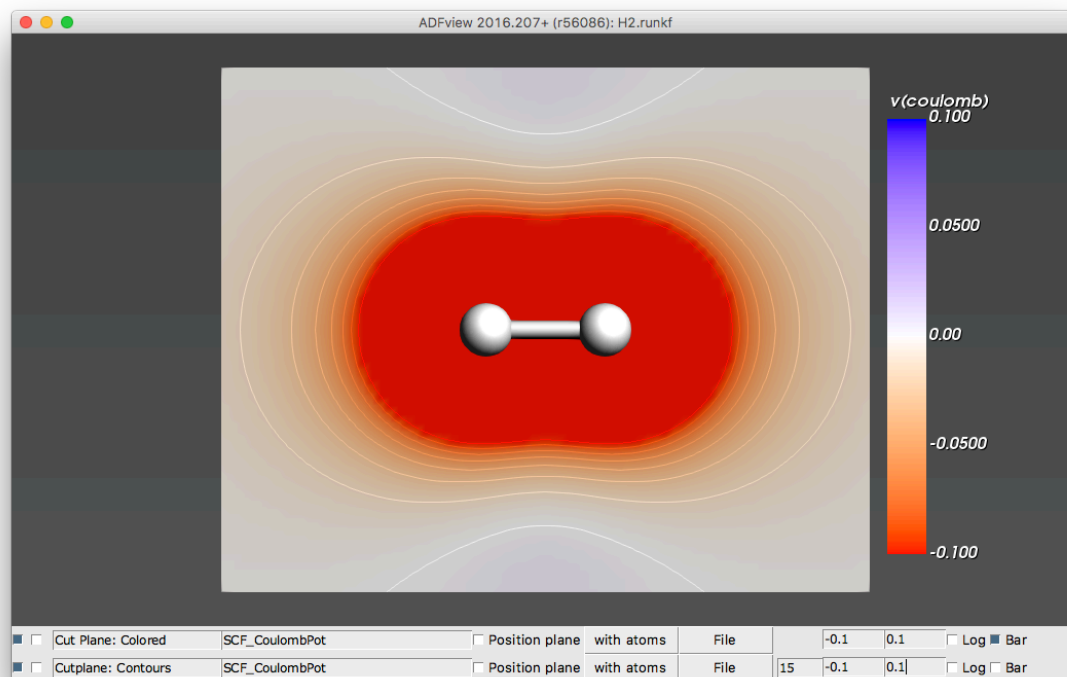

Note: The sign convention for potentials in **BAND** is the opposite to the **ADF** sign convention.

SCF_CoulombDeformation (v(coulomb/deformation)) The Coulomb potential originating from the (overall neutral) deformation density.
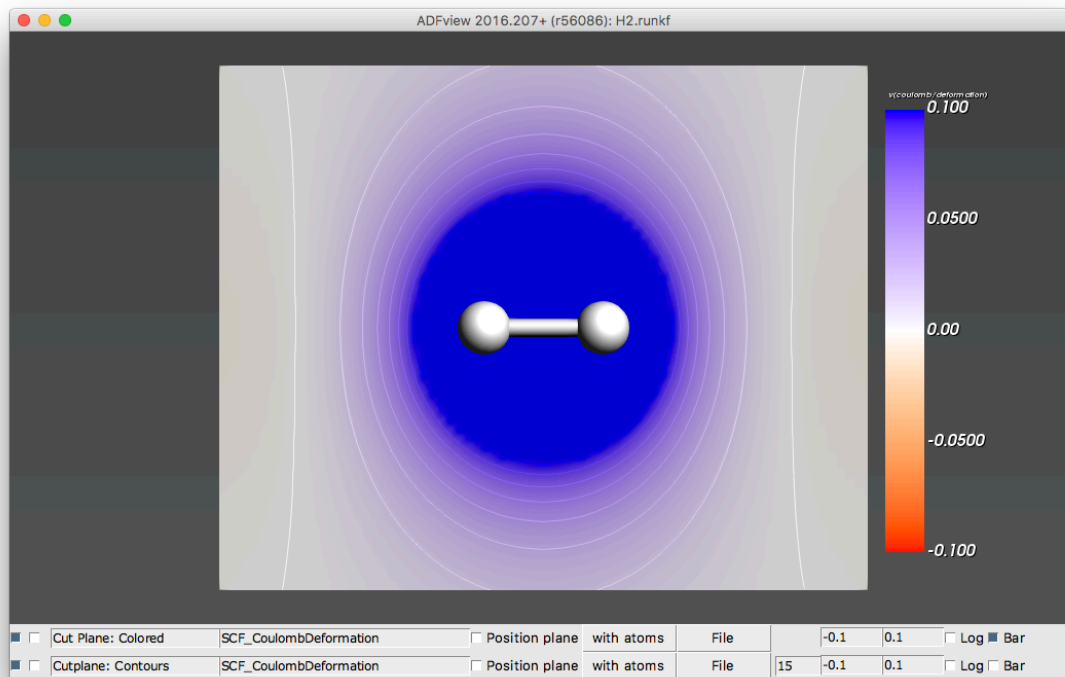

xc pot (vxc(rho)) The Exchange Correlation (XC) potential. Electrons are *attracted* by negative XC potentials (just like they are *attracted* by the negative nuclear Coulomb potential)
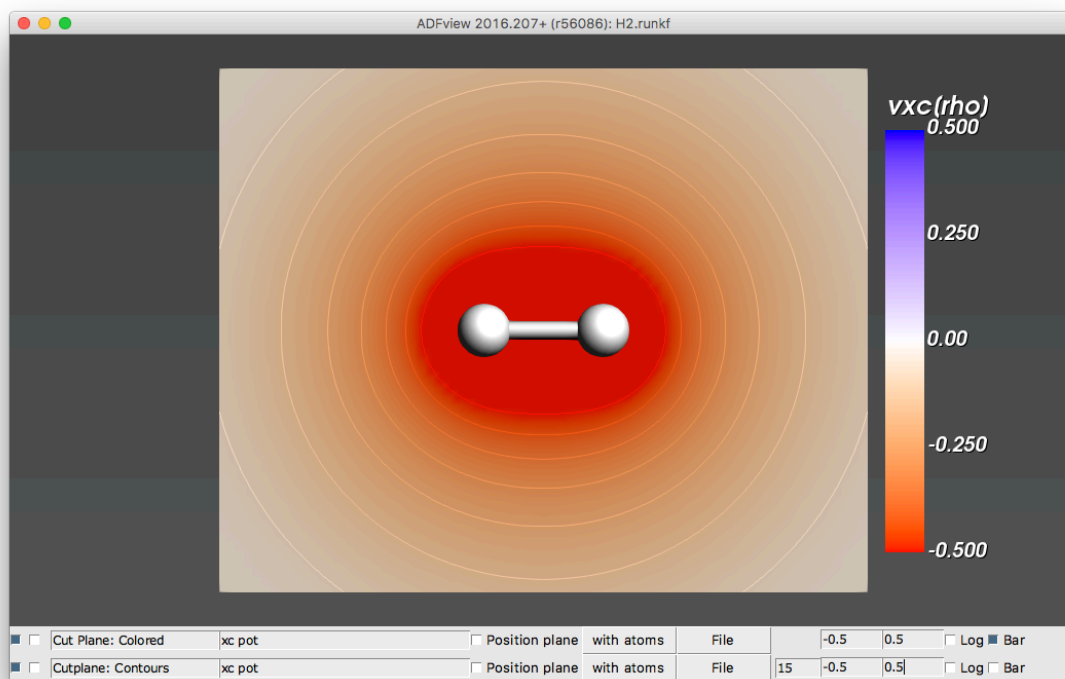

Orbitals (occupied/virtual) The Kohn-Sham orbitals.

Note: Be aware that there is an over-all arbitrariness in the sign of the orbitals

---

Here we show the occupied and first virtual orbital of H_2.
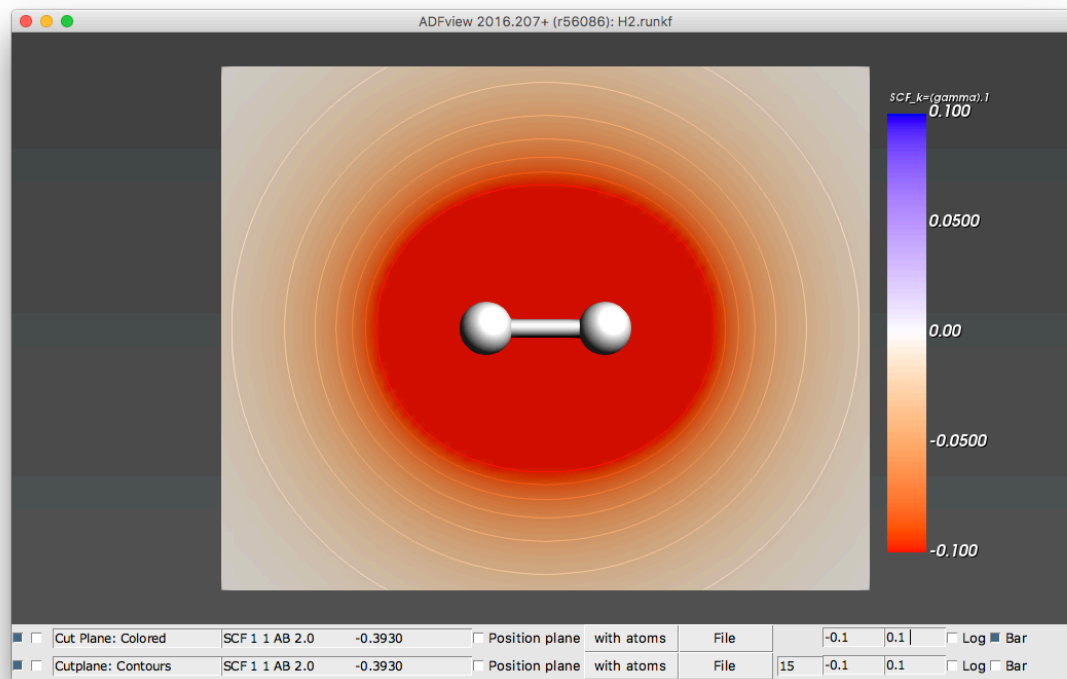

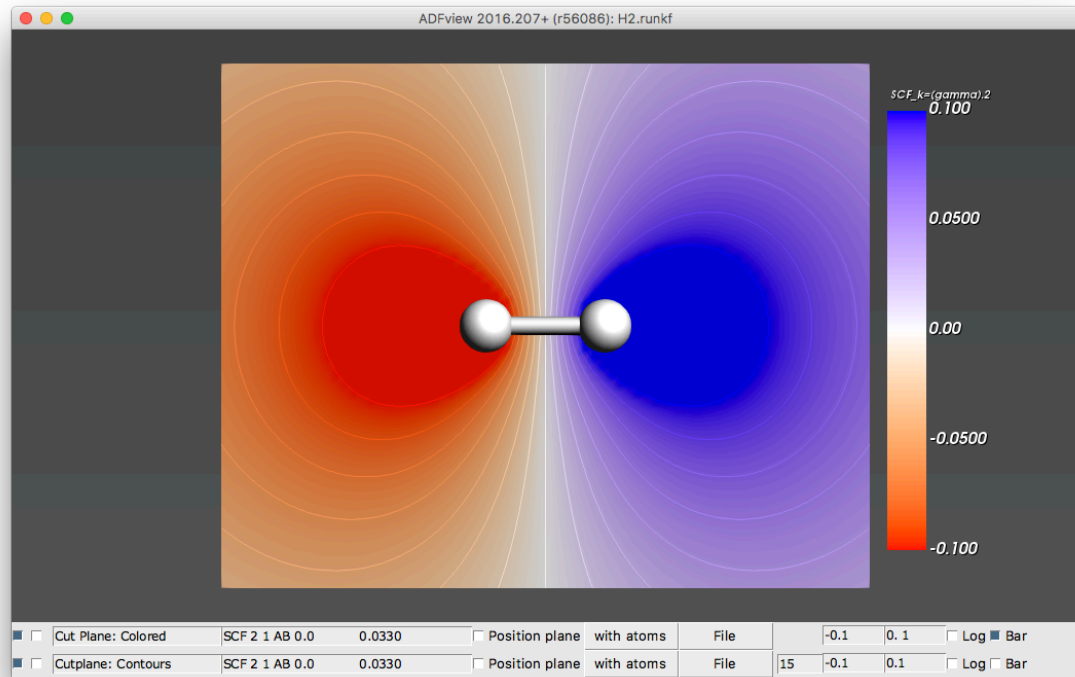

ELECTRONIC TRANSPORT (NEGF)

See also:

Some examples are available in the `$AMSHOME/examples/band` directory and are discussed in the Examples section.

Note: In the BAND-GUI it is possible to choose between three NEGF methods (*flavors*):

Self consistent This is the internal BAND-NEGF implementation, which is described in this page.

Self consistent + align This is the internal BAND-NEGF implementation with an extra alignment-run (workflow step 3a)

Non self consistent Computationally cheap method, equivalent to the DFTB-NEGF approach with H and S matrix elements computed by BAND (instead of DFTB).

7.1 Transport with NEGF in a nutshell

The **Non-Equilibrium Green's Functions** formalism (**NEGF**) is a theoretical framework for modeling electron transport through nano-scale devices. Electron transport is treated as a one-dimensional coherent scattering process in the "scattering region" for electrons coming in from the electrodes:
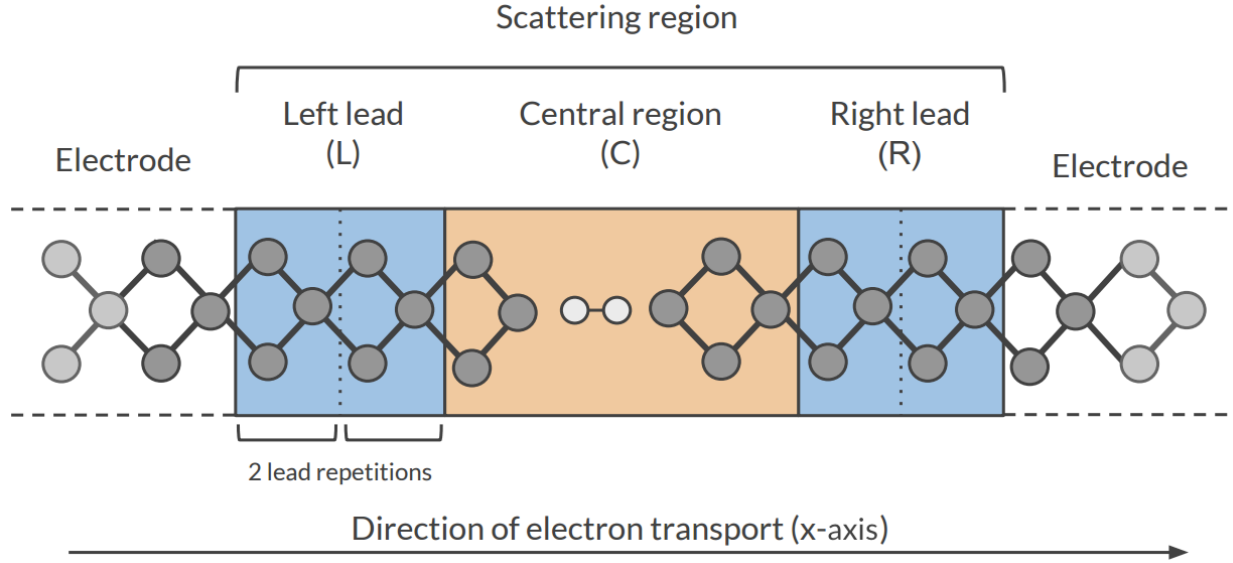

Our goal is to compute the **transmission function** $T(E)$, which describes the rate at which electrons of energy E are transferred from the left electrode to the right electrode by propagating through the scattering region. From the transmission function we can calculate the electric current for given **Bias Voltage** V applied between the electrodes:

$$I(V) = \frac{2e}{h} \int_{-\infty}^{\infty} T(E, V) \left(f(E - \mu_L) - f(E - \mu_R) \right) dE$$

where $f(E)$ is the Fermi-Dirac distribution function for a given temperature, and μ_L (μ_R) is $\epsilon_F + eV/2$ ($\epsilon_F - eV/2$), ϵ_F being the Fermi energy of the electrodes.

The transmission function $T(E)$ can be computed from the **Green's function** of our system.

The Green's function $G(E)$ of the scattering region is obtained solving the following equation:

$$(ES - H)G(E) = I$$

where S is the overlap matrix, H is the Hamiltonian and I is the identity matrix. The Hamiltonian is composed as follows (**L**, **C** and **R** denote the **left lead**, the **central region** and the **right lead** respectively):

$$H = \begin{pmatrix} H_L + \Sigma_L & H_{LC} & 0 \\ H_{LC} & H_C & H_{RC} \\ 0 & H_{RC} & H_R + \Sigma_R \end{pmatrix}$$

The two *self-energies* Σ_L and Σ_R model the two semi-infinite electrodes.

The transmission function $T(E)$ can be calculated from the Green's function $G(E)$ and the so-called *broadening matrices* $\Gamma_L(E)$ and $\Gamma_R(E)$:

$$T(E) = Tr[G(E)\Gamma_R(E)G(E)\Gamma_L(E)]$$

The broadening matrix being

$$\Gamma_L(E) = -2\Im\Sigma_L(E)$$

7.1.1 Self consistency

The density matrix is determined self consistently[1]:

$$P_{\text{in}} \rightarrow H_{KS} \xrightarrow{\text{shifts}} H_{\text{aligned}} + \Sigma_L(E) + \Sigma_R(E) \rightarrow G(E) \xrightarrow{\int de} P_{\text{out}}$$

From a guess of the density matrix the corresponding KS Hamiltonian is calculated. This Hamiltonian is aligned, and then the NEGF Hamiltonian in the complex plane is constructed by adding the self energies, representing the influence of the electrodes. From the resulting Green's function a new density matrix follows.

From the difference between input and output density a next input is guessed. This is repeated until the input and output densities converge.

For the alignment of the Hamiltonian there are two shifts. The first shift aligns the potential in the leads to the electrodes.

$$\text{shift 1} = \frac{1}{n} \sum_{\text{i in lead}}^{n} \frac{H_{ii}^{TB} - H_{ii}^{KS}}{S_{ii}}$$

The second and usually smaller shift results from the alignment run. A shift Δ is applied globally

$$H_{ij}^{\text{aligned}} = H_{ij} + \Delta S_{ij}$$

7.1.2 Contour integral

Without bias the density matrix follows from

$$P(\mu) = -\frac{1}{\pi} \int_{-\infty}^{\infty} de \ f(e, \mu) \ \Im G(e)$$

As the Green's function is singular on the real axis we add a small imaginary value (**eta**) to the energy. Still, the integrand will be very wild function, and it is numerically better to do a contour integral instead.
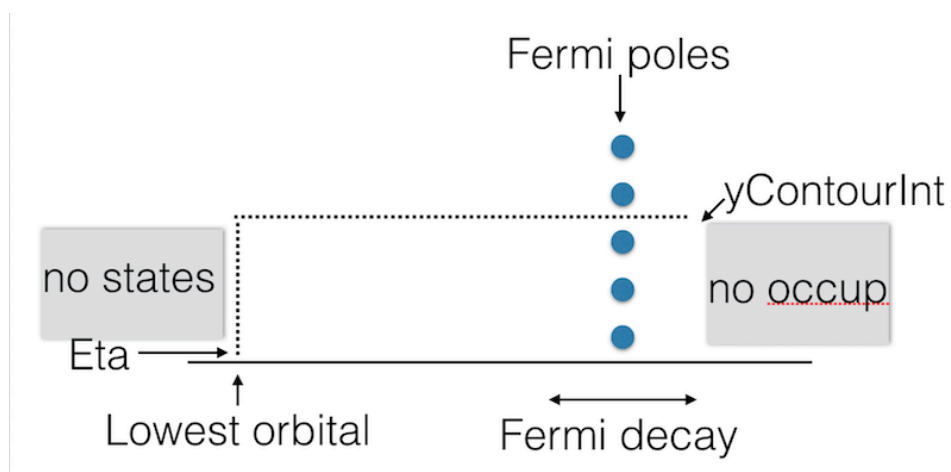

Fig. 7.1: Figure: BAND uses a rectangular contour in the complex energy plane to integrate the (integrand of the) density matrix. The integrand also needs to be evaluated in the enclosed FD poles (three in this picture).

---

[1] C. J. O. Verzijl and J. M. Thijssen *DFT-Based Molecular Transport Implementation in ADF/BAND*, J. Phys. Chem. C, 2012, 116 (46), pp 24393–24412 (https://doi.org/10.1021/jp3044225).

7.1.3 Gate potential

There is no direct key for the gate potential. You can model this with the *FuzzyPotential* (page 43) key. Setting up the gate potential for NEGF is most conveniently done with the GUI.

7.1.4 Bias potential
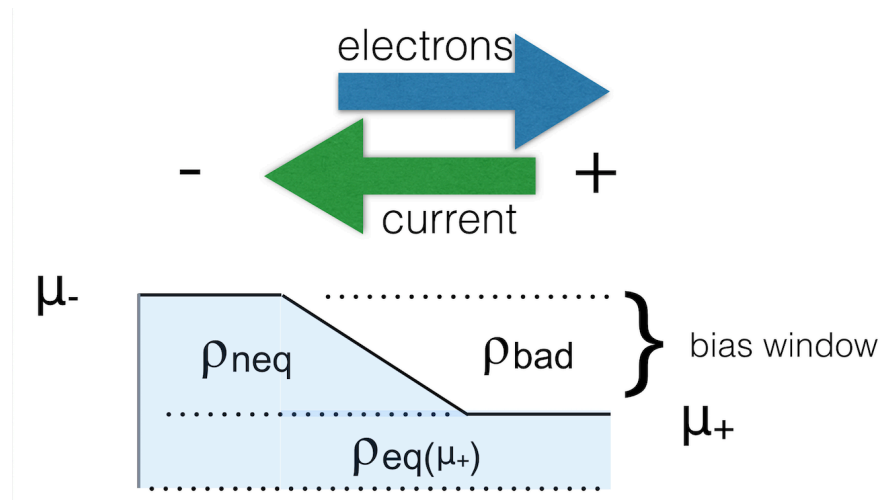

When there is a bias specified there are two important things to keep in mind.

First of all you need to define a ramp potential. In the negative lead this should have the value +V/2 and in the negative lead -V/2. The ramp should smoothly go from one to the other value. For metals one could start the ramp at the surface atoms of the lead material. For semi-conductors it is less clear. The ramp potential can be specified with the *FuzzyPotential* (page 43) key. The GUI can be helpful here.

Secondly, the expression for the density is different from the zero-bias case:

$$\rho = \rho_{\text{eq}}(\mu_+) + \rho_{\text{neq}}$$

The first (equilibrium) term is calculated with a contour integral as before, the second (non-equilibrium) part cannot be calculated with a contour integral. Instead, an integral in the complex plane (close to the real axis) is performed, the range covering the bias energy window.

See also:

PhD Thesis (https://www.scm.com/wp-content/uploads/Verzijl2012.pdf) of C. Verzijl (BAND-NEGF developer)

7.2 Workflow

The computation of the transmission function $T(E)$ within the BAND-NEGF[?] formalisms requires three or four individual simulations.

Tip: Use ADFInput (GUI) to set up your BAND-NEGF calculation (see the BAND-NEGF GUI tutorial)

---

1): Lead calculation A 1D-periodic BAND calculation of the lead (including *StoreHamiltonian2* (page 151)):
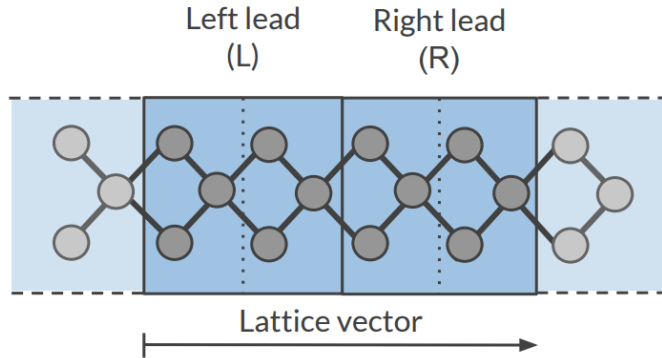

A tight binding (TB) representation is calculated for the overlap ($S(R = 0)$ and $S(R = a)$) and Fock matrix ($H(R = 0)$ and $H(R = a)$). This is not an approximation provided that the functions do not extend beyond the neighboring cells. You should choose a sufficiently large super cell for this to be true. For this reason we recommend setting the *SoftConfinement* (page 54) Quality to Basic, thus reducing the range of the functions.

2): SGF calculation A small program that determines the fermi energy ϵ_F corresponding to the TB representation, and the specified temperature. This fermi energy is typically a bit higher than the one from the lead calculation. This also tests the contour integration.

3a): Alignment run (optional) The idea is to fill the central region with bulk material. Then one expects to have zero charge in the central region. In practice this is not exactly true. In the alignment run the shift is determined that makes the central region neutral. This global shift is to be used in the next run.

3b): Transport calculation Computes the NEGF transmission function $T(E)$. The density matrix is determined fully self-consistently. Without alignment (3a) one should set `NEGF%ApplyShift2` to `False`.

To get the current as a function of bias potential you need to repeat calculation 3b for a various bias potentials.

7.3 Input options

7.3.1 SGF Input options

SGF is a small separate program. An input looks like:

```
$AMSBIN/sgf    << eor
TITLE Test for NEGF inputs
SAVE SIGMA
SURFACEGF
    SCMCode True
    KT 0.001
    ContourQuality normal
END
eor
```

It looks for a file `RUNKF` and the output is a file named `SigmaSCM`. The only important parameter is KT which is the Boltzmann constant times the temperature in Hartree. The other parameter of interest is the ContourQuality, which can be set to Basic,Normal,Good,VeryGood, or Excellent.

7.3.2 NEGF Input options (no bias)

The NEGF functionality is controlled by the NEGF block key.

```
NEGF
   LeadFile string
   SGFFile string
   ContourQuality [basic | normal | good | verygood]
   EMin float
   EMax float
   NE integer
End
```

NEGF

> **Unit** eV
>
> **Description** The maximum energy for the transmission grid (with respect to the Fermi level of the lead)

NE

>>> **Type** Integer

>>> **Default value** 100

>>> **Description** The number of energies for the transmission energy grid.

The following are expert / technical options:

```
NEGF
   CheckOverlapTol float
   Eta float
   ApplyShift1 Yes/No
   ApplyShift2 Yes/No
   YContourInt float
   DEContourInt float
End
```

NEGF

>>> **Type** Block

>>> **Description** Options for the NEGF (non-equilibrium green function) transport calculation.

>> **CheckOverlapTol**

>>> **Type** Float

>>> **Default value** 0.01

>>> **Description** BAND checks how well the TB overlap matrix S(R=0) represents the overlap matrix in the lead region. Elements corresponding to the outer layer are neglected, because when using a frozen core they have bigger errors.

>> **Eta**

>>> **Type** Float

>>> **Default value** 1e-05

>>> **Description** Small value used for the contour integral: stay at least this much above the real axis. This value is also used for the evaluation of the Transmission and dos.

>> **ApplyShift1**

>>> **Type** Bool

>>> **Default value** Yes

>>> **Description** Apply the main shift, obtained from comparing matrix elements in the leads with those from the tight-binding run. Strongly recommended.

>> **ApplyShift2**

>>> **Type** Bool

>>> **Default value** Yes

>>> **Description** Apply the smaller alignment shift. This requires an extra alignment run. Usually this shift is smaller.

>> **YContourInt**

>>> **Type** Float

>>> **Default value** 0.3

> **Description** The density is calculated via a contour integral. This value specifies how far above the real axis the (horizontal part of the) contour runs. The value is rounded in such a way that it goes exactly halfway between two Fermi poles. There is a trade off: making it bigger makes the integrand more smooth, but the number of enclosed poles increases. For low temperatures it makes sense to lower this value, and use a smaller deContourInt.

DEContourInt

> **Type** Float
>
> **Default value** -1.0
>
> **Description** The energy interval for the contour grid. Defaults depends on the contour quality

7.3.3 NEGF Input options (with bias)

With a bias potential there are some extra keys.

```
NEGF
   BiasPotential float
   NonEqDensityMethod integer
   BoundOccupationMethod integer
   YRealaxisInt float
   DERealAxisInt float
End
```

NEGF

> **Type** Block
>
> **Description** Options for the NEGF (non-equilibrium green function) transport calculation.

BiasPotential

> **Type** Float
>
> **Default value** 0.0
>
> **Description** Apply a bias potential (atomic units). Can be negative. One has to specify the ramp potential with the FuzzyPotential key. This is mostly conveniently done with the GUI.

NonEqDensityMethod

> **Type** Integer
>
> **Default value** 1
>
> **Description** See text.

BoundOccupationMethod

> **Type** Integer
>
> **Default value** 1
>
> **Description** See text. Only relevant with NonEqDensityMethod equal 2 or 3.

YRealaxisInt

> **Type** Float
>
> **Default value** 1e-05
>
> **Description** The non-Equilibrium density is calculated near the real axis.

DERealAxisInt

>> **Type** Float

>> **Default value** -1.0

>> **Description** The energy interval for the real axis grid. Defaults depends on the contour quality.

NonEqDensityMethod Let us introduce some terms[2]. First of all the total density in the bias window (ignoring occupation)

$$D = \frac{1}{2\pi} \int A \left(f_- - f_+ \right)$$

And then there are the side resolved densities

$$D_{+/-} = \frac{1}{2\pi} \int A_{+/-} \left(f_- - f_+ \right)$$

The issue here is that the side resolved densities do not sum to the total one

$$D = D_+ + D_- + D_{\text{bound states}}$$

The NonEqDensityMethod is about how these integrals are calculated . With option 1, or 2 a contour integral is used for D: they are essentially the same. However, when choosing option 2, you can choose a BoundOccupationMethod, leading to other physics. If set to 3, the total density in the bias window (D) will be calculated near the real axis: this way one avoids the possibility of a negative nr. of bound states (deviating from[?]).

BoundOccupationMethod Only relevant with NonEqDensityMethod equal 2 or 3. If set to one, the density of bound states (ignoring occupation) is simply multiplied by a half. If set to two, atoms closer to the negative lead will get a higher occupation[?]. Atoms coupled to the right lead will have a low occupation. For this we recommend setting NonEqDensityMethod to 3, to avoid a possible negative number of bound states.
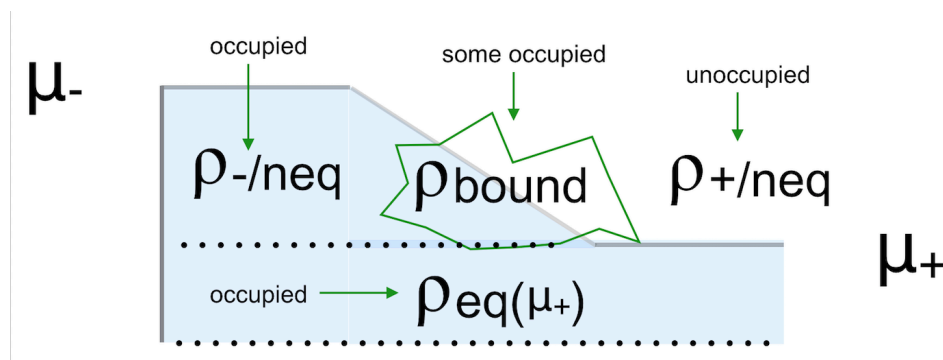

Fig. 7.2: Figure: The non-equilibrium density consists of three parts: the left and right parts (ρ-/neq and ρ+/neq) and the bound states (ρbound). We want to know the occupied part.

Setting the method BoundOccupationMethod to 1, leads to

$$\rho = \rho(\mu_+) + \rho_{\text{-/neq}} + \frac{1}{2} \rho_{\text{bound}}$$

By setting the method to 2, each atom gets its own weight in the density matrix

$$\rho_{ij} = \rho_{ij}(\mu_+) + \rho_{\text{-/neq}} + \sqrt{w_i w_j} \rho_{ij}^{\text{bound}}$$

---

[2] Rui Li, Jiaxing Zhang, Shimin Hou, Zekan Qian, Ziyong Shen, Xingyu Zhao, Zengquan Xue, *A corrected NEGF + DFT approach for calculating electronic transport through molecular devices: Filling bound states and patching the non-equilibrium integration*, Chemical Physics 336 (2007) 127-135 (https://doi.org/10.1016/j.chemphys.2007.06.011).

with[?]

$$w_i = \frac{\text{Tr}[D_-]_i}{\text{Tr}[D_-]_i + \text{Tr}[D_+]_i}$$

These weights are the same for all functions on an atom. The intended effect is: bound states that are coupled more strongly to the negative electrode get a higher occupation than the ones that are coupled more strongly to the positive electrode.

To summarize here are three reasonable settings

NonEqDensityMethod	BoundOccupationMethod	intention
1	1	Multiply the bound states with a half
2	2	Occupy bound states with atom-resolved w_i
3	2	… and prevent a negative nr. of bound states

To get the current from a calculation you can use amsprep:

```
$AMSBIN/amsreport RUNKF 'NEGF%current'
```

7.3.4 NEGF Input options (alignment)

For the (optional) alignment run there are some extra keys.

```
NEGF
   DoAlignment Yes/No
   Alpha float
   AlignChargeTol float
   CDIIS Yes/No
End
```

NEGF

> **Type** Block
>
> **Description** Options for the NEGF (non-equilibrium green function) transport calculation.

DoAlignment

> **Type** Bool
>
> **Default value** No
>
> **Description** Set this to True if you want to do an align run. Between the leads there should be lead material. The GUI can be of help here.

Alpha

> **Type** Float
>
> **Default value** 1e-05
>
> **Description** A charge error needs to be translated in a potential shift. DeltaV = alpha * DeltaQ

AlignChargeTol

> **Type** Float
>
> **Default value** 0.1

Description In an alignment run you want to get the number of electrons in the center right. This number specifies the criterion for that.

CDIIS

    Type Bool

    Default value No

    Description Make the normal DIIS procedure aware of the align charge error

7.4 Troubleshooting

The self consistent approach, unique to BAND, may be difficult to converge. If this is true for the alignment run it can be decided to skip this run. For the final transport run, here are some tips / considerations.

- Use a SZ basis for the metal atoms

- Restart (the density matrix) from the result of a smaller (such as the SZ) basis. (See "*Save* (page 161) DensityMatrix" and the *Restart* (page 153) key)

- Restart (the density matrix) from the result obtained with a smaller bias (only relevant for calculations with bias potential).

- Setting NEGF%BoundOccupationMethod to 2 (and NEGF%NonEqDensityMethod to 3) might help. Note that this affects the physics: you are differently occupying the bound states.

- Use a better NEGF%ContourQuality (there comes a computational price tag with this).

If everything fails it is possible to use BAND in a **non-self consistent way**, similar to the way DFTB-NEGF works. This option is available via the GUI.

7.5 Miscellaneous remarks on BAND-NEGF

- You should make sure that your results are converged with respect to the number of lead repetitions; the results should not change significantly if you increase the number of lead repetitions.

- It's good practice to include at least one lead repetition in the central region.

7.5.1 Store tight-binding Hamiltonian

Let us consider a Fourier transformation of a 1D Bloch matrix

$$S(R = na) = \int_k e^{-ikR} S(k)$$

In (the tight-binding) case that the functions do not extend beyond the neighboring cells only S(R=0) and S(R=a) are nonzero. (And S(R=-a) is equivalent to S(R=a))

```
StoreHamiltonian2 Yes/No
```

StoreHamiltonian2

    Type Bool

    Default value No

Description determine the tight-binding representation of the overlap an fock matrix. Used for (at least) NEGF.

Adding StoreHamiltonian2 to the input cause band to determine the tight-binding representation of the overlap an fock matrix. Currently this only works for 1D periodic systems. For the overlap matrix you will get two parts. The first $S(R = 0)$ is the (symmetric) overlap matrix of atoms in the unit cell. The second $S(R = a)$ is a non symmetric matrix describing the coupling of functions in the central cell with functions in its right neighboring cell. On the RUNKF file you will find the TB representations of the overlap and Hamiltonian stored in the 'Matrices' section as "S(R)" and "H(R)", being dimensioned (nBas,nBas,2).

EXPERT OPTIONS

8.1 Restarts

The main results of a BAND calculation are stored in the rkf file. If you save this file you can use it to restart your calculation. The input for the restart calculation is essentially the same, except for some extra keys, like `Restart`, `Grid`, and `DensityPlot`.

Plots of the density (and many other symmetric properties) can can be obtained with the key `DensityPlot`. Density and orbital plot restarts require the specification of the `Grid` key. With the subkey `SCF` you can start the SCF procedure with the last solution from the restart file. This can be useful if the SCF did not converge or if you want to compute some post-SCF properties (e.g. the *DOS* (page 121) or the *band structure* (page 125)). Similarly, a geometry optimization can be restarted with the subkey `GeometryOptimization` You can use the geometry of a previous calculation.

Usually the input for a restarted job is the same as for the original calculation, with some extra options, described in this section.

Some examples are available in the `$AMSHOME/examples/band` directory and are discussed in the Examples section.

Example: Restart SCF for properties calculation (page 217)
Example: Restart the SCF (page 211)
Example: Properties on a grid (page 218)
Example: DOS and BandStructure from a previous calculation (page 221)

8.1.1 Restart key

```
Restart
   File string
   SCF Yes/No
   DensityPlot Yes/No
   OrbitalPlot Yes/No
   NOCVdRhoPlot Yes/No
   NOCVOrbitalPlot Yes/No
   UseDensityMatrix Yes/No
   BandStructure Yes/No
   DOS Yes/No
End
```

Restart

> **Type** Block
>
> **Description** Tells the program that it should restart with the restart file, and what to restart.

File

>> **Type** String

>> **Default value**

>> **Description** Name of the restart file.

SCF

>> **Type** Bool

>> **Default value** No

>> **GUI name** Restart: SCF

>> **Description** Continue the SCF procedure using the orbital coefficients and occupations from the restart file.

DensityPlot

>> **Type** Bool

>> **Default value** No

>> **Description** Goes together with the DensityPlot block and Grid blocks

OrbitalPlot

>> **Type** Bool

>> **Default value** No

>> **Description** Goes together with the OrbitalPlot and Grid

NOCVdRhoPlot

>> **Type** Bool

>> **Default value** No

>> **Description** Goes together with the NOCVdRhoPlot and Grid blocks.

NOCVOrbitalPlot

>> **Type** Bool

>> **Default value** No

>> **Description** Goes together with the NOCVOrbitalPlot and Grid blocks.

UseDensityMatrix

>> **Type** Bool

>> **Default value** No

>> **Description** If set to True: For restarting the SCF the density matrix will be used. Requires you to set 'Save DensityMatrix' in the previous run.

BandStructure

>> **Type** Bool

>> **Default value** No

>> **Description** Calculate the band structure from a previos calculation. Does not work with model potentials and Hubbard.

DOS

Type Bool

Default value No

Description Calculate the DOS from a previous calculation. Does not work with model potentials and Hubbard.

8.1.2 Grid

The Grid block is used for restart options `OrbitalPlot`, `DensityPlot`, `NOCVOrbitalPlot` and `NOCVdRho-Plot`. There are two ways to define your grid. The most easy way is to use the Type key, which automatically generates a grid around the atoms in the unit cell:

```
Grid
   Type [coarse | medium | fine]
End
```

Grid

      Type Block

      Description Options for the regular grid used for plotting (e.g. density plot). Used ICW the restart option.

    Type

        Type Multiple Choice

        Default value coarse

        Options [coarse, medium, fine]

        Description The default regular grids.

One alternative is to specify everything by hand via the 'UserDefined' sub-block.

```
Grid
   UserDefined header # Non-standard block. See details.
      ...
   End
End
```

Grid

      Type Block

      Description Options for the regular grid used for plotting (e.g. density plot). Used ICW the restart option.

    UserDefined

        Type Non-standard block

        Description One can define the regular grid specification in this block. See example. Default unit is Bohr

The following input would create a cube from (-1,-1,-1) to (1,1,1) bohr:

```
Grid
  UserDefined
    -1 -1 -1 ! Starting point
    1 0 0 0.1   ! vec1 and dvec1
```

```
    0 1 0 0.1   ! vec2 and dvec2
    0 0 1 0.1   ! vec3 and dvec3
    20 20 20    ! nr. of steps along three directions
  End
End
```

Note: The grid is specified in bohr

One can also specify a text file from which the grid is imported:

```
Grid
   FileName string
End
```

Grid

> **Type** Block
>
> **Description** Options for the regular grid used for plotting (e.g. density plot). Used ICW the restart option.

> **FileName**
>
> > **Type** String
> >
> > **Default value**
> >
> > **Description** Read in the grid from a file. The file format of the grid is: three numbers per line (defining the x, y and z coordinates of the points).

8.1.3 Plots of the density, potential, and many more properties

```
DensityPlot # Non-standard block. See details.
   ...
End
```

DensityPlot

> **Type** Non-standard block
>
> **Description** Plots of the density. Goes together with the Restart%DensityPlot and Grid keys.

The DensityPlot block goes together with the `Restart%DensityPlot` and `Grid` keys. Example input:

```
...
Restart
   File my_file.rkf
   DensityPlot
End

Grid
   Type Coarse
End

DensityPlot
   rho(fit)
```

```
   vxc[rho]
End
...
```

After such a run you get a TAPE41 file that you should rename to my.t41, and view with AMSview.

The most common properties to plot are:

- `rho(fit)` The fitted density.

- `v(coulomb)` The Coulomb potential.

- `vxc[rho(fit)]` the XC potential (using the fitted density)

- `vxc[rho]` XC potential of the exact density

- `rho` The density

- `|gradRho|` The norm of the gradient of the density

- `tau` The symmetric kinetic energy density

- `LDOS` The local density of states. (See *LDOS key* (page 160))

- `elf[rho]` The electron localization function

- `X` The *Electron energy density function* (page 161) from Ref[12] . Equivalently `X(fit)` may be used as an approximation, employing the density fit.

Some more specialized options are:

- `rho(deformation/fit)` the fitted deformation density

- `rho(atoms)` The density of the startup atoms

- `v(coulomb/atoms)` The Coulomb potential of the start density

- `s[rho]` Reduced density gradient. Common ingredient for XC functionals

- `s[rho(fit)]` Same as above, now for the fit density

- `alpha[rho]` Ingredient for some meta-GGAs

In the BAND example directory there is the *Frags_COCu* (page 265) example which shows how this can be used in combination with the `Fragment` key.

8.1.4 Orbital plots

```
OrbitalPlot # Non-standard block. See details.
   ...
End
```

OrbitalPlot

> **Type** Non-standard block

> **Description** Goes together with the Restart%OrbitalPlot and Grid keys. See Example.

The OrbitalPlot block goes together with the `Restart%OrbitalPlot` and `Grid` keys. Example input:

---

[1] Stefano Racioppi, Martin Rahm. In-Situ Electronegativity and the Bridging of Chemical Bonding Concepts. Chemistry – A European Journal 72 (2021): 18156-18167 (https://doi.org/10.1002/chem.202103477)

[2] Stefano Racioppi, Per Hyldgaar, Martin Rahm. Quantifying Atomic Volume, Partial Charge, and Electronegativity in Condensed Phases. The Journal of Physical Chemistry C 128.9 (2024): 4009 (https://doi.org/10.1021/acs.jpcc.3c07677)

```
...
Restart
   File my_file.rkf
   OrbitalPlot
End

Grid
   Type Coarse
End

OrbitalPlot
   1 Band 5 8  ! for k-point 1 plot bands 5 to 8
   5 Band 6    ! for k-point 5 plot band 6
   6 -0.2 +0.3 ! for k-point 6 plot bands between -0.2 and +0.3 a.u. w.r.t Fermi level
End
...
```

After such a run you get a TAPE41 file that you should rename to my.t41, and view with AMSview.

8.1.5 Induced Density Plots of Response Calculations

```
ResponseInducedDensityPlot # Non-standard block. See details.
   ...
End
```

ResponseInducedDensityPlot

> **Type** Non-standard block

> **Description** Goes together with Restart%ResponseInducedDensityPlot and Grid.

`ResponseInducedDensityPlot` `(block-type)` The ResponseInducedDensityPlot block goes together with the `Restart%ResponseInducedDensityPlot` and `Grid` keys. In the BAND example directory there is the *TD-CDFT for MoS2 Monolayer* (page 250) example that shows how this can be used. Example input:

```
...
Restart
   File my_file.rkf
   ResponseInducedDensityPlot
End

Grid
   Type Coarse
End

ResponseInducedDensityPlot
   XCOMPONENT 5 8  ! plot x component of induced densities
                   ! for frequencies number 5 to 8
   YCOMPONENT 6    ! plot y component of induced densities
                   ! for frequency number 6
   ZCOMPONENT 1    ! plot z component of induced densities
                   ! for frequency number 1
End
...
```

After such a run you get a TAPE41 file that you should rename to my.t41, and view with AMSview.

> **Attention:** The plotting capability works only with response calculation RUNKF files based on the *NewResponse* (page 97) method!

8.1.6 NOCV Orbital Plots

```
NOCVOrbitalPlot # Non-standard block. See details.
   ...
End
```

NOCVOrbitalPlot

> **Type** Non-standard block
>
> **Description** Goes together with the Restart%NOCVOrbitalPlot and Grid keys. See example.

The NOCVOrbitalPlot blockg oes together with the `Restart%NOCVOrbitalPlot` and `Grid` keys. See example *PEDANOCV_MgO+CO* (page 282). Example input:

```
...
Restart
   File my_file.rkf
   NOCVOrbitalPlot
End

Grid
   Type Coarse
End

NOCVOrbitalPlot
   1 Band 5 8 ! for k-point 1 plot NOCV Orbitals 5 to 8
End
...
```

After such a run you get a TAPE41 file that you should rename to my.t41, and view with AMSview.

8.1.7 NOCV Deformation Density Plots

```
NOCVdRhoPlot # Non-standard block. See details.
   ...
End
```

NOCVdRhoPlot

> **Type** Non-standard block
>
> **Description** Goes together with the Restart%NOCVdRhoPlot and Grid keys. See example.

The NOCVdRhoPlot blockg oes together with the `Restart%NOCVdRhoPlot` and `Grid` keys. See example *PEDANOCV_MgO+CO* (page 282). Example input:

```
...
Restart
   File my_file.rkf
   NOCVdRhoPlot
```

```
End

Grid
    Type Coarse
End

NOCVdRhoPlot
    1 Band 5 8 ! for k-point 1 plot NOCV deformation densities 5 to 8
End
...
```

After such a run you get a TAPE41 file that you should rename to my.t41, and view with AMSview.

8.1.8 LDOS (STM)

The local density of states (LDOS) represents a partial density, (see wikipedia (https://en.wikipedia.org/wiki/Density_of_states#Local_density_of_states)): it is the density arising from states within an energy window.

```
LDOS
    DeltaNeg float
    DeltaPos float
    Shift float
End
```

LDOS

> **Type** Block
>
> **Description** Local Density-Of-States information. This can be used to generate STM images in the Tersoff-Hamann approximation (see https://doi.org/10.1103/PhysRevB.31.805)

> **DeltaNeg**
>
> > **Type** Float
> >
> > **Default value** 0.0001
> >
> > **Unit** Hartree
> >
> > **Description** Lower bound energy (Shift-DeltaNeg)

> **DeltaPos**
>
> > **Type** Float
> >
> > **Default value** 0.0001
> >
> > **Unit** Hartree
> >
> > **Description** Upper bound energy (Shift+DeltaPos)

> **Shift**
>
> > **Type** Float
> >
> > **Default value** 0.0
> >
> > **Unit** Hartree
> >
> > **Description** The energy bias with respect to the Fermi level.

Integrating from minus infinity (DeltaNeg=1e6) to the fermi level (DeltaPos=0) produces the total (valence) density.

The local density of states is integrated over the resulting interval. Example of an LDOS restart:

```
Restart
   File my_file.rkf
   DensityPlot
End

Grid
   Type Coarse
End

DensityPlot
   LDOS
End

LDOS
   Shift     0.1
   DeltaNeg 0.001
   DeltaPos 0.0
End
```

According to this example, we restart from the result file of a previous calculation. The calculation will generate a file TAPE41 which can be viewed with AMSview. (Rename the file to my.t41)

See also *Restart* (page 153), and *DensityPlot* (page 156).

8.1.9 Electron Energy Density

The electron energy density is defined as[?]

$$X(r) = -\left\{ \tfrac{1}{2} \sum_i^{\text{occ}} \nabla\psi_i \cdot \nabla\psi_i - \tfrac{1}{4}\nabla^2\rho - V_{\text{effective}}\rho \right\}$$

It can be obtained by requesting X or X(fit) in a restart, see also *Restart* (page 153), and *DensityPlot* (page 156).

8.1.10 Save

```
Save string
```

Save

> **Type** String
>
> **Recurring** True
>
> **Description** Save scratch files or extra data that would be otherwise deleted at the end of the calculation. e.g. 'TAPE10' (containing the integration grid) or 'DensityMatrix'

8.1.11 Restarting the DOS and/or BandStructure

Perhaps you did a calculation, optimizing the geometry, and now want to see the band structure and partial DOS. This can be achieved by using `Restart%DOS` and `Restart%BandStructure`. This way you can easily refine your plots, or solve a missing DOS problem, without having to repeat the whole SCF.

With the restarting of the DOS there is the special possiblity to use a better k-grid than was used during the SCF. Whereas the Band structure is not very k-grid sensitive, the DOS depends strongly on the k-grid. A common problem is that of missing DOS: where there are bands there is no DOS, being an artifact of insufficient k-sampling. Using only a better k-grid for the DOS calculation may produce a DOS that is almost as good as if a full calculation (SCF and DOS) was done with the better k-grid. Notice that the effective potential in such a restart with a better k-grid corresponds to the k-grid as was used during the SCF. Therefore the band structure is not affected by using a better k-grid for the restart. See also the *RestartDosAndBandStructure* (page 221) example.

This figure shows that the DOS obtained from restarting with a better k-grid is very close to the one obtained with a full calculation with the better k-grid.
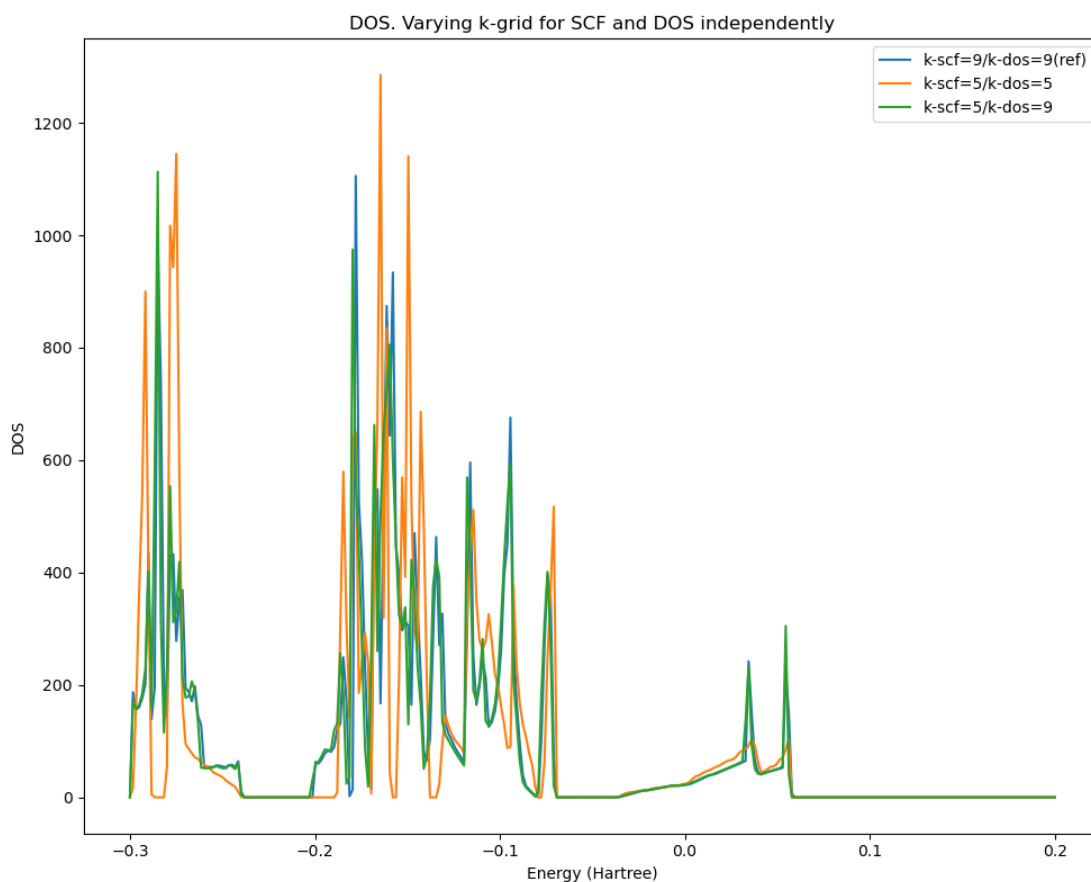

Fig. 8.1: DOS of a Mo3WSeS7 slab. The best result is when using a 9x9 k-grid for both the SCF and the DOS calculation (blue curve). Using a worse 5x5 grid for both the SCF and the DOS produces a quite different DOS (amber). Doing the SCF with the coarser 5x5 grid and restarting the DOS with the finer 9x9 grid gives the green DOS, matching closely, and mostly hides, the best DOS (blue).

Below we show how a missing DOS issue can be solved by either using a better k-grid, or more efficiently by only using a better k-grid for the DOS (using the `DOS%Restart` option)

While restarts for plotting should be done with the `Grid` key, the restarting of the DOS/BandStructure should not.
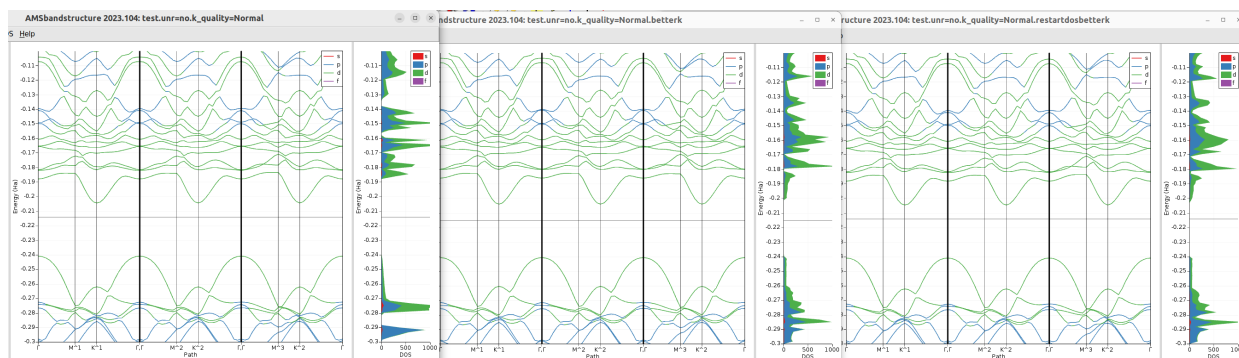

Fig. 8.2: Illustration of the missing DOS problem for a Mo3WSeS7 slab. Left panel: calculation with a normal k-grid. We clearly see DOS missing in the energy intervals -0.20 to -0.19, and -0.29 to -0.28. Middle panel: using a good k-grid, now the missing DOS appears. The band structure is not much affected, only the lowest band at Gamma being slightly higher with a good k-grid. Right panel: restart from the normal k-grid calculatoin, but using a good k-grid for the restart. The restarted DOS is very close to the one obtained with the good k-grid for both the SCF and the DOS.

8.2 References

8.3 Symmetry

The symmetry of the system is automatically detected. Normally the symmetry of the initial system is maintained. One can lower the symmetry with the `Symmetry` key. In such cases the keyword `POTENTIALNOISE` can force the solution away from the initial symmetry.

Whether or not symmetry should be used can be controlled vial the `UseSymmetry` key

```
UseSymmetry Yes/No
```

UseSymmetry

> **Type** Bool
>
> **Default value** Yes
>
> **Description** Whether or not to exploit symmetry during the calculation.

One can also select a sub set of symmetry operators:

```
SubSymmetry integer_list
```

SubSymmetry

> **Type** Integer List
>
> **Description** The indices of the symmetry operators to maintain.

To get the indices of the symmetry operators, you should first run the calculation with the following options added to your input:

```
print symmetry
stopafter gemtry

and then you look in the output for (here the first four operators are listed)
```

```

 1)       1.000   0.000   0.000       0.000        0.000    1.0      1
          0.000   1.000   0.000       0.000        0.000
          0.000   0.000   1.000       0.000        1.000

 2)       1.000   0.000   0.000       0.000        0.000    1.0      1
          0.000   1.000   0.000       5.400        0.000
          0.000   0.000   1.000       0.000        1.000

 3)       1.000   0.000   0.000       5.400        0.000    1.0      1
          0.000   1.000   0.000       0.000        0.000
          0.000   0.000   1.000       0.000        1.000

 4)       1.000   0.000   0.000       5.400        0.000    1.0      1
          0.000   1.000   0.000       5.400        0.000
          0.000   0.000   1.000       0.000        1.000
```

from this list you should select the desired operators and use that in your final calculation, for example:

```
SubSymmetry 1 7 21 31
```

8.3.1 Symmetry breaking for SCF

```
PotentialNoise float
```

PotentialNoise

> **Type** Float
>
> **Default value** 0.0001
>
> **Description** The initial potential for the SCF procedure is constructed from a sum-of-atoms density. Added to this is some small noise in the numerical values of the potential in the points of the integration grid. The purpose of the noise is to help the program break the initial symmetry, if that would lower the energy, by effectively inducing small differences between (initially) degenerate orbitals.

8.4 Advanced Occupation Options

By default the levels are occupied according to the aufbau principle. In some cases it is possible to create holes below the Fermi level or uneven occupation for alpha and beta electrons with the Occupations (Γ-only) and alternatively the EnforcedSpinPolarization (for an arbitrary number of k-points) key.

```
Occupations # Non-standard block. See details.
   ...
End
```

Occupations

       Type Non-standard block

       Description Allows one to input specific occupations numbers. Applies only for calculations that use only one k-point (i.e. pseudo-molecule calculations). See example.

Example:

```
OCCUPATIONS
   1 occupations_alpha {// occupations_beta}
End
```

- `occupations_beta` and the separating double slash (//) must not be used in a spin-restricted calculation.

- `occupations_alpha/beta` is a sequence of values assigned to the states ('bands') in energy ordering.

```
ElectronHole
   BandIndex integer
   SpinIndex integer
End
```

ElectronHole

       Type Block

       Description Allows one to specify an occupied band which shall be depopulated, where the electrons are then moved to the Fermi level. For a spin-restricted calculation 2 electrons are shifted and for a spin-unrestricted calculation only one electron is shifted.

    BandIndex

          Type Integer

          Description Which occupied band shall be depopulated.

    SpinIndex

          Type Integer

          Description Defines the spin of the shifted electron (1 or 2).

See the example *Si_ElectronHole* (page 294)

Finally, also the `Convergence%StartWithMaxSpin` influences (indirectly) the final state. Running for instance the H2 molecule with a PBE functional preserves the triplet state through the SCF (not being the ground state).

TROUBLESHOOTING

9.1 Recommendations

9.1.1 Model Hamiltonian

Relativistic model

By default we do not use relativistic effects. The best approximation is to use spin-orbit coupling, however that is computationally very expensive. The scalar relativistic option comes for free, and for light elements will give very similar results as non-relativistic theory, and for heavy ones better results w. r. t. experiment. We recommend to always use this (scalar ZORA). To go beyond to the spin-orbit level can be important when there are heavy elements with p valence electrons. Also the band gap appears quite sensitive for the spin-orbit effect.

XC functional

The default functional is the LDA, that gives quite good geometries but terrible bonding energies. GGA functionals are usually better at bonding energies, and among all possibilities the PBE is a common choice. Using a GGA is not a lot more expensive than using plain LDA. For the special problem of band gaps there are a number *Model Hamiltonians* (page 13) available (eg. TB-mBJ and GLLC-SC). The *Unrestricted* (page 28) option will be needed when the system is not closed shell. For systems interacting through dispersion interactions it is advised to use the *Grimme corrections* (page 16). Unfortunately there is no clear-cut answer to this problem, and one has to try in practice what works best.

9.1.2 Technical Precision

See also:

- *Which basis set should I use?* (page 47)

- *Recommendations for k-space* (page 60)

The easiest way to control the technical precision is via the *NumericalQuality* (page 45) key. One can also independently tweak the precision of specific technical aspects, e.g.:

```
BeckeGrid
  Quality Good ! tweak the grid
End
KSpace
  Quality Good  ! tweak the k-space grid
End
ZlmFit
```

```
  Quality Normal   ! tweak the density fit
End
SoftConfiment
  Quality Basic   ! tweak the radial confinement of basis functions
End
```

Here are per issue hints for when to go for a better quality (but it is by no means complete)

- **BeckeGrid**: Increase quality if there are geometry convergence problems. Also negative frequencies can be caused by an inaccurate grid.

- **KSpace**: Increase quality for metals

- **ZlmFit**: Increase quality if the SCF does not converge.

- **SoftConfinment**: Increase quality for weakly bonded systems, such as layered materials

9.1.3 Performance

The performance is influenced by the model Hamiltonian and basis set, discussed above. Here follow more technical tips.

Reduced precision

One of the simplest things to try is to run your job with NumericalQuality Basic. For many systems this will work well, and it can be used for instance to pre-optimize a geometry. However, it can also cause problems such as problematic SCF convergence, geometry optimization, or simply bad results. See above how to tweak more finely the *Technical Precision* (page 167).

Memory usage

Another issue that is the choice CPVector (say the vector length of you machine) and the number of k-points processed together during the calculation of the parameters. In the output you see the used value

```
            =========================
            = Numerical Integration =
            =========================

TOTAL NR. OF POINTS                                  4738
BLOCK LENGTH                                          256
NR. OF BLOCKS                                         20
MAX. NR. OF SYMMETRY UNIQUE POINTS PER BLOCK          35
NR. OF K-POINTS PROCESSED TOGETHER IN BASPNT           5
NR. OF SYMMETRY OPERATORS (REAL SPACE)                48
SYMMETRY OPERATORS IN K-SPACE                         48
```

If you want to change the default settings you can specify the CPVector and KGRPX keywords. The optimal combination depends on the calculation, on the machine. Example

```
CPVector 512
KGRPX 3
```

Note: bigger is not necessarily better.

Reduced basis set

When starting work on a large unit cell it is wise to start with a DZ basis. With such a basis, one can test for instance the quality of the k-space integration. However, for most properties, the DZ basis is probably not very accurate. You can next go for the DZP (if available) or TZP basis set, but that may be a bit of overkill.

Performance on machines with many cores

When running a not so big system (1000 basis functions) on a single machine with many cores you may observe a large discrepancy between the cpu and the elapsed time.

In the logfile you see for instance

```
cyc=  1 err=1.99E+00 meth=m nvec= 1 mix=0.0750 cpu=   3s ela=  27s fit=3.75E-02
```

indicating that the cpu time is 3 seconds, but the ela(psed) time was 27 seconds, much longer.

The (likely) reason is the use of shared arrays when calculating the matrix elements, which requires locking within a node.

A way to avoid this problem is to emulate as if you are using multiple nodes. Say you have a 128 core machine and add to your script

```
export SCM_SHAR_NCORES=8

$AMSBINB/ams ...
```

and tell ams that a node is made of 8 cores. When you run the job (on a single node 128 core machine) you should see in the logfile

```
AMS 2020.203  RunTime: Jan16-2021 18:05:27  Nodes: 16  Procs: 128
```

and now it is as if you are running on 16 nodes with 8 cores each. This requires more memory but this only becomes an issue with large system (10000 basis functions). In this example we need 16 times as much memory. You can use other values for the SCM_SHAR_NCORES variable, and it also works when using more than one (physical) node.

Since ams2021 a physical node may already be split automatically when ams recognizes that it uses multiple slots.

Is memory an issue for your calculation? The number of basis functions is printed in the output

```
                            *****************************
                            *   S C F   P R O C E D U R E   *
                            *****************************

Nr. of basis functions              1424
Nr. of core functions                592
Nr. of fit functions                   0
Nr. of symmetry unique K-points        1
Valence charge                    640.00
```

You take this number squared and multiply this with 16 (complex number) and you have the size of a single matrix. Then you multiply with 10 or 30 to get an estimate of the memory needed (per "node"). You should compare is to the memory per core times the nr, of cores per node.If it does not fit then the performance drop will be even more dramatic, as the system needs to swap.

Systems with many basis functions are either systems with many atoms (1000) or systems with heavy elements and a small core (gold slab).

9.1.4 Band gap calculations

The simplest method is to compare the difference between the HOMO and the LUMO to the experimental band gap. It is quite well known that regular GGAs, such as the PBE functional, underestimate the band gap this way. However, there are some functionals designed to make the HOMO LUMO gap resemble the experimental gap. These are either MetaGGAs or model potentials (for which there is no energy expression). When using MetaGGAs it is recommended to use a small frozen core, as the core orbitals will be calculated at the LDA level. The KSpace%Quality should be set to Good. The TZP basis set gives already good gaps.

We have calculated with these settings for some functionals the band gap on the Crowley (https://doi.org/10.1021/acs.jpclett.5b02870) test set (leaving out transition metal oxides and 2D slabs). The spin orbit change to the band gap was calculated only at the PBE level and used for all other functionals.
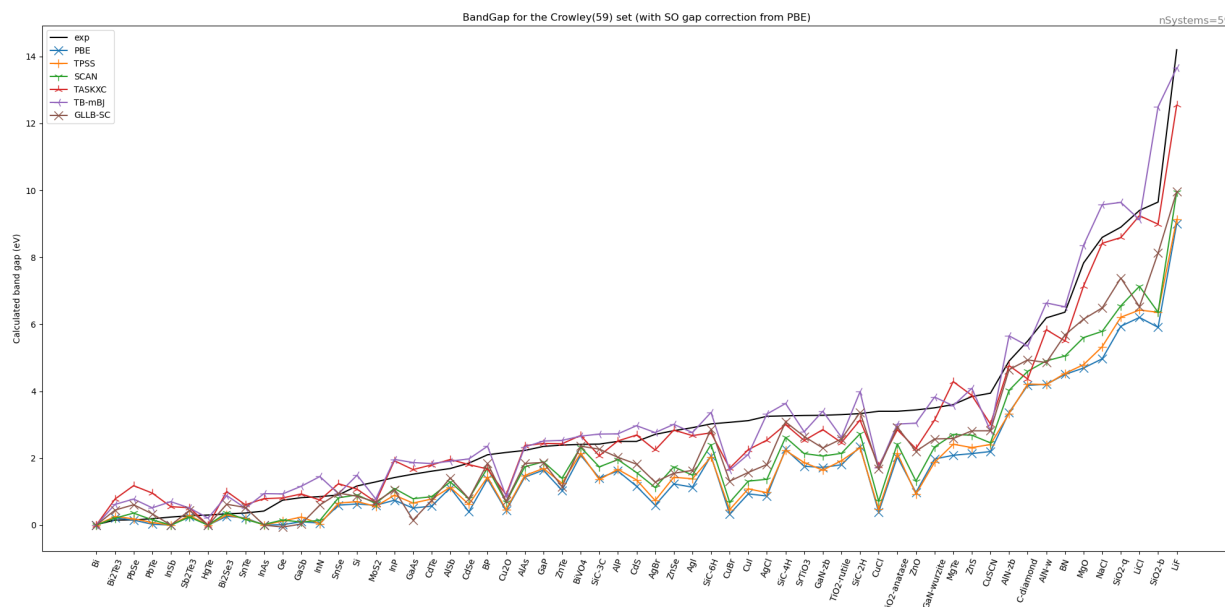

Table 9.1: Error statistics for calculated band gaps

XC	MAE	MARE
PBE	1.374	0.520
TPSS	1.288	0.489
SCAN	1.042	0.425
TASKXC	0.469	0.510
TB-mBJ	0.462	0.414
GLLB-SC	0.850	0.459

We can conclude that the TB-mBK functional appears to be best one, but the TASKXC is also doing quite well.

Here is the (Band engine) input used for the TASKXC functional

```
Basis Type=TZP Core=Small    # for metaGGA a small core is recommended
KSpace Quality=Good
XC
   metaGGA TASKXC
End
BandStructure Enabled=yes    # this gives you also the gap estimated along the
→standard path through the BZ zone (in the text output)
```

The gap is either obtained from the kf file from the Variable BandStructure%BandGap, or from the text output.

in a plams script both can be obtained this way

```
try:
    gap = job_result.readrkf("BandStructure","BandGap", "band")

    gap=Units.convert(gap, 'hartree', 'eV')
except:
    gap=0.0

try:
    grep_string=job_result.grep_output('band gap from band-structure')
    assert len(grep_string) == 1
    words=grep_string[0].split(':')
    gap_from_bs=float(words[-1].strip())
except:
    gap_from_bs=0.0
```

Usually the difference is very small between the two methods.

9.2 Troubleshooting

9.2.1 SCF does not converge

Some systems are more difficult to converge than others. A Pd slab for instance is easier to converge than an Fe slab. Generally, what you do in a problematic case is to go for more conservative settings. The two main option are to decrease `SCF%Mixing` and/or `DIIS%Dimix`.

```
SCF
    Mixing 0.05 ! more conservative mixing
End

Diis
    DiMix 0.1 ! also more conservative strategy for DIIS procedure
    Adaptable false ! disable automatic changing of dimix
End

Convergence
    Degenerate Default ! For most calculations this is quite a good idea anyway
End
```

An other option is to first run the system with a SZ basis, which may be easier to converge. Then you can *Restart* (page 153) the SCF with a larger basis set from this result.

Sometimes SCF convergence problems are caused by bad precision. An indication of this is when there are many iteration after the HALFWAY message. The simplest thing to try is to see whether increasing the `NumericalAccuracy` helps. Specifically an insufficient quality of the **density fit** may cause problems. For systems with heavy elements the quality of the **Becke grid** may also play a role. Another potential problem is using **only one k-point**.

Next thing to try is the MultiSecant method. This one comes at no extra cost per SCF cycle compared to the DIIS method.

```
SCF
  Method MultiSecant
End
```

(continues on next page)

```
MultiSecantConfig
   ! put here optional keywords to tweak the MultiSecant method
End
```

An alternative is to try a **LIST** method. For sure the cost of a single SCF iteration will increase, but it may reduce the number of SCF cycles, see *Diis%Variant* (page 75).

```
Diis
  Variant LISTi ! invoke the LISTi method
End
```

For heavy elements the use of a small or no frozen core may complicate the SCF convergence.

Finite temperature during geometry optimization

Often systems are more easy to converge when applying a finite electronic temperature. By doing so your energy will deviate from the ground state. If you are optimizing, say, a fancy molecule over a Ni slab, then you do not care too much about this when the geometry is not nearly converged yet (when the gradients are still big).

Using so-called automations, it is possible to instruct band to use a higher electronic temperature in the beginning of a geometry optimization, and a lower one at the end. Similarly you can allow for more loose SCF convergence at the start of the geometry optimization. You specify such "automations" inside the ams-level GeometryOptimization block, for example

```
GeometryOptimization

  EngineAutomations
     Gradient variable=Convergence%ElectronicTemperature InitialValue=0.01␣
→FinalValue=0.001 HighGradient=0.1 LowGradient=1.0e-3
     Iteration variable=Convergence%Criterion InitialValue=1.0e-3 FinalValue=1.0e-6␣
→FirstIteration=0 LastIteration=10
     Iteration variable=SCF%Iterations InitialValue=30 FinalValue=300␣
→FirstIteration=0 LastIteration=10
  End
End
```

Let us concentrate on the first "automation". What this will do is the following.

- At the first step Convergence%ElectronicTemperature (kT) will be set to InitialValue, i.e. 0.01. (Temperatures are entered as kT in Hartree.)

- If at any step the gradient is bigger than HighGradient the temperature will be InitialValue

- If at any step the gradient is smaller than LowGradient the temperature will be FinalValue, i.e. 0.001

- If the gradient is in between HighGradient and LowGradient, a linear interpolation is done (on a logarithmic scale)

- At the last calculation FinalValue will be used, even if the geometry did not converge

Another trigger for automation is the number of geometry steps taken, shown in the two automations with "Iteration".

Let us look at the second automation.

- At the first geometry the Convergence%Criterion is relaxed to 1.0e-3.

- After the tenth geometry step this will be 1.0e-6

- In between an interpolated value will be used

The third automation shows that you can also automate SCF%Iterations. Currently only three band keywords can be automated this way.

9.2.2 Geometry does not converge

One thing that you should make sure is that at least the **SCF converges**. If that is so, then maybe the **gradients are not accurate enough**. Here are some settings to improve the accuracy of the gradients

```
RadialDefaults
  NR 10000   ! more radial points
End

NumericalQuality Good
```

9.2.3 Lattice optimization does not converge for gga

What can help is use to use analytical stress rather than numerical stress. There are three things to change for this to work.

```
SoftConfinement Radius=10.0

StrainDerivatives Analytical=yes

XC
  libxc PBE       # may also be another GGA, but not a metaGGA
End
```

Here follows an explanation why. The SoftConfinement is set to a fixed value, rather than one depending on the lattice vectors, because that is not covered by the analytical stress code. The normal value for this radius is 10, except for 3D bulk systems with a small lattice where it is set to something like the size of the lattice vector.

The other two bits are needed to trigger the use of analytical stress (which are strain derivatives of the energy). The use of the libxc library is needed, as it affords derivatives required for the stress.

9.2.4 I see two band gaps, which one is best?

The band gap is the difference between the bottom of the conduction band (BOCB) and the top of the valence band (TOVB).

It is now important to distinguish two methods to arrive at the information of TOVB, BOCB, and hence the gap. The first is the one coming from the analytical k-space integration scheme determining the fermi level and occupations, let us call this the interpolation method. The second one is a strictly post SCF method that cannot be used to determine the fermi energy and occupations. This is about calculating the bands along a path through the BZ assuming a certain fixed density/potential. Let us call this second method the from band structure method.

The advantage of the "band structure" method is that is you can use a very dense sampling of k-points along the chosen path (DeltaK). Normally this is the better way to get the gap, but you assume that both the TOVB and BOCB are on the specified path, which is not a mathematical necessity (although in practice very often true). The advantage of the "interpolation" method that is really follows the (quadratically interpolated) bands over the whole BZ. Typically the spacing between k-points is much larger than DeltaK from the plot (as the number of points for the first grows cubic and the latter only linear).

Finally the gap printed in the kf file is the one from the "interpolation method".

9.2.5 Band structure does not match the DOS

This problem may be related to the previous topic. The DOS is derived from true k-space integration called the "interpolation method" in the previous topic: it samples through interpolation the whole BZ. For the band structure plot a single line is used, and typically a much denser grid can be afforded. So make sure that the DOS is converged with respect to the KSpace%Quality paramter: try a better (or worse) value.

Ultimately a converged DOS may still not match a band structure as it is possible that the chosen line misses some features (it does not cover the whole BZ).

Finally the energy grid for the DOS may be too coarse, it can be made smaller with DOS%DeltaE.

9.2.6 Missing core bands or DOS peaks in amsbands

If you do a calculation on, say, an Al chain you may expect a core like band and corresponding DOS peak at -1500 eV. To achieve this you first need to set the frozen core to None. Even then it still does not show up, because by default BandStructure%EnergyBelowFermi is 10 Hartree (~300 eV). If you set it to something large (10000) you will now see the 1s band showing up near -1500 eV, however the corresponding DOS peak appears invisible… that is, until you zoom in the y-axis appropriately. If the DeltaE used for the dos is smaller than the height of a pixel the peak will be invisible, or very faint.

9.2.7 Negative frequencies in phonon spectra

When doing a phonon calculation one sometimes encounter unphysical negative frequencies. There are two likely causes: either the **geometry was not in the minimum geometry**, or the **step size** used in the Phonon run is too large. Also **general accuracy** issues may be the cause, such as numerical integration, k-space integration and fit error.

9.2.8 Too much scratch disk space is used

For systems having either many basis functions or many k-points the required disk space demand can grow and te program can crash. The needed scratch space is overwhelmingly determined by (temporary) matrices written to disk. How this is done is determined by an input key. In case of this problem set

```
Programmer Kmiostoragemode=1   ! 1 means: fully distributed, 2 is the default meaning␣
→distributed only within (ShM) nodes
```

You can increase the available scratch disk space by using more nodes. The number of nodes (according to the AMS definition) is printed in the output and logfile

```
AMS 2021.105  RunTime: Feb08-2022 19:27:17  ShM Nodes: 1  Procs: 24
```

and you can search for "ShM Nodes".

9.2.9 Basis set dependency

A calculation aborts with the message: dependent basis. It means that for at least one k-point in the BZ the set of Bloch functions, constructed from the elementary basis functions is so close to linear dependency that the numerical accuracy of results is in danger. To check this, the program computes, for each k-point separately, the overlap matrix of the Bloch basis (normalized functions) and diagonalizes it. If the smallest eigenvalue is zero, the basis is linearly dependent. (Negative values should not occur at all!). Given the limited precision of numerical integrals and other aspects in the calculation, you are bound for trouble already if the smallest eigenvalue is very small, even if not exactly zero. The program compares it against a criterion that can be set in input (key `Dependency` option *Bas*).

If you encounter such an error abort, you are strongly advised not to adjust the criterion so as to pass the internal test: there were good reasons to implement the test and to set the default criterion at its current value. Rather, you should adjust your basis set. There are two ways out: using confinement or removing basis functions.

Using confinement

Usually the dependency problem is due to the diffuse basis functions. This is especially so for highly coordinated atoms. One way to reduce the range of the functions is to use the Confinement key. In a slab you could consider to use confinement only in the inner layers, and to use the normal basis to the surface layers. The idea is that basis functions of the surface atoms can describe the decay into the vacuum properly, and that inside the slab the diffuseness of the functions is not needed. If all the atoms of the slab are of the same type, you should make a special type for the inner layers: simply put them in a separate Atoms block. The confinement can be specified per type.

9.2.10 Frozen core too large

BAND calculates the overlap matrix of the core functions, and this should approximate the unit matrix. To validate that this is the case two numbers are checked: the smallest eigenvalue of the overlap matrix (which should be larger than `Dependency%Core`) and the maximum absolute deviation of diagonal elements from one, which should be smaller than 1-`Dependency%Core`. When the deviation is larger then the frozen-core overlap criterion the program stops. The default (`Dependency%Core = 0.80`) is fairly tolerant. The safest solution is to choose a smaller *Frozen core* (page 49), this can also be controller per atom type (element) or per region, see *More Basis input options* (page 52). In the text output the name of the element is printed that seeems to be most responsible for the frozen core too large error. For performance reasons, however, this may not be the preferred option. In practice you might still get reliable results by setting the criterion to 0.5, see the *Dependency* (page 90) block. For the *5d* transition metals, for instance, you can often freeze the 4f orbital (using the more tolerant setting), thus reducing the basis set considerably. If you loosen the criterion we strongly advise you to compare these results to a calculation with a smaller core. Such tests can be performed with a smaller unit cell or with a lower quality for the `KSPACE` block key.

9.2.11 requested kgrid appears to break the symmetry

Band creates by default a regular k-grid. In the case of 3D the size is determined by k1,k2, and k3. Normally the values are derived from KSpace%Quality and the length of the trhee reciprocal lattice vectors. If a lattice vector is long enough the corresponding k may be set to 1, which is a special value. For instance if you get for your system a 3x5x1 grid it means that effectively we have a 2 dimensional problem.

This can be problematic when there is symmetry. Perhaps there are symmetry relations between the "remaining" two vectors and the "removed" lattice vector. If such is the case the error "kgrid appears to break the symmetry" is raised.

You can either disable the symmetry

```
UseSymmetry No # inside the BandEngine block
```

or you can figure out what the automatic values for k1,k2, and k3 are.

In case of the error you see in the output

```
grid method with params               3               3               1
ERROR: requested kgrid appears to break the symmetry
        there are two solutions
        1) Disable symmetry for the engine
        2) Avoid a automatic grid like 3x3x1. Try a better KSpace%Quality.
```

So that in this case a 3x3x1 grid was chosen. In this example you probably want to increase k3

```
KSpace
    Regular
        NumberOfPoints 3 3 3 # specify k1,k2,k3 "by hand"
    End
end
```

9.3 Various issues

9.3.1 Understanding the logfile

In practice you will look often at the logfile to see whether the calculation is going fine. Here is a logfile for a single point calculation.

```
<Oct16-2019> <11:44:37>   AMS 2019  RunTime: Oct16-2019 11:44:37  Nodes: 1  Procs: 4
<Oct16-2019> <11:44:37>   BAND 2019  RunTime: Oct16-2019 11:44:37  Nodes: 1  Procs: 4
<Oct16-2019> <11:44:37>   All basis functions smoothly confined at radius: 10.0
<Oct16-2019> <11:44:37>   >>>> RADIAL
<Oct16-2019> <11:44:38>   >>>> POINTS
<Oct16-2019> <11:44:38>   >>>> KPNT
<Oct16-2019> <11:44:39>   >>>> CELLS

<Oct16-2019> <11:44:44>  copy eigensystem
<Oct16-2019> <11:44:45>  NORMAL TERMINATION
```

There are three different phases. The first phase is the preparation phase. The second phase is the SCF procedure. The third part is the properties phase. Particularly important are the SCF CONVERGENCE and NORMAL TERMINATION messages.

The preparation phase is the part up to "start of SCF loop". The first entries are usually not very costly. The section PREPAREBAS is about the overlap matrix, core orthogonalization, and the transformation to the orthogonal basis. In PREPAREHAM the fixed part of the Hamiltonian is calculated (mostly kinetic energy).

Let us take a closer look at a line during the SCF.

```
<Jul10-2018> <18:24:59>  cyc=  3 err=4.35E-02 meth=d nvec= 2 mix=0.2200 cpu=   1s␣
↪ela=   1s fit=1.60E-02
```

The meaning of cyc is the iteration number, so it is the third iteration. The self consistent error (err) is 4.35E-02. The method (meth) to guess the density for the next cycle is d, meaning DIIS, being a linear combination (nvec) of two vectors. The density is biased (mix) by 0.2 towards output densities. The SCF cycle took 1 second of cpu time (per core), and needed 1 seconds of real time. Finally the error of the density fitting was 1.60E-02

9.3.2 Breaking the symmetry

In some cases you want to break the symmetry. An example of this is when you want to get the antiferromagnetic state of Fe. Another common example is when you want to apply geometry constraints on atoms.

The easiest way to do this is of course to disable all symmetry, see *UseSymmetry key* (page 163), but this might make your calculation more expensive than is needed. A bit more elegant way is to define separate types for the equivalent atoms. Here follows an example input for antiferromagnetic iron

```
! The two iron atoms have different "types" to break the symmetry
System
    Atoms
      Fe.a   0.0    0.0    0.0
      Fe.b  -1.435 -1.435  1.435
    End
End

Lattice
   -1.435  1.435  1.435
    1.435 -1.435  1.435
    2.87   2.87  -2.87
End

...
...

Band Engine

  ...
  CONVERGENCE
      CRITERION 1.0e-4
      Degenerate default
      SpinFlip 2  ! Flip (startup) spin density at second atom
  END
  ...
EndEngine
```

Another solution is to use the expert SYMMETRY keyword.

9.3.3 Labels for the basis functions

You see the labels for the basis functions in for instance the DOS section of the output. The labels are also used in combination with options like `Print Eigens` and `Print OrbPop`.

What do the labels look like? A normal atomic basis function, i.e. a numerical orbital or a Slater type orbital, gets a label like <atom number>/<element>/<orbital type>/<quantum numbers description>/<exp in sto>

Example with a Li and a H atom:

```
1/LI/NO/1s
1/LI/NO/2s
1/LI/STO/2s/1.4
1/LI/STO/2p_y/1.3
1/LI/STO/2p_z/1.3
1/LI/STO/2p_x/1.3
2/H/NO/1s
```

```
2/H/STO/1s/1.9
...
```

Core states will just get simple numbers as labels:

```
CORE STATE 1
CORE STATE 2
```

With the `Fragment` key you can give meaningful names to the fragment option, see `Fragment%Labels` and `Dos-Bas`.

9.3.4 Reference and Startup Atoms

The formation energy of the crystal is calculated with respect to the reference atoms. BAND gives you the formation energy with respect to the spherically symmetric spin-*restricted* LDA atoms. If you want the program to do the spin-unrestricted calculation for the atoms you can give key Unrestricted the extra option Reference. We do not recommend this as it would give you the false (except in special cases) feeling that you've applied the right atomic correction energy so as to obtain the 'true' bonding energy with respect to isolated atoms. The true atomic correction energy is the difference in energy between the used artificial object, i.e. the spherically symmetric, spin-restricted atom with possibly fractional occupation numbers, and the appropriate multiplet state. The spin-*un*restricted reference atom would still be spherically symmetric, with possibly fractional occupations: it would only have the probably correct (Hund's rule) net spin polarization.

The startup density is normally the sum of the restricted atoms. In case you do an unrestricted calculation you may want to get the sum of the unrestricted atoms as startup density by giving key Unrestricted the extra option StartUp. This does not always provide a better startup density since all atoms will have their net-spins pointing up. If a frozen core is used this option can sometimes lead to a negative valence density, because the frozen core is derived from the restricted atom. The program will stop in such a case.

No matter what reference or startup atoms you use, core orbitals and NOs originate always from the restricted free-atom calculation, because we don't want a spatial dependence of the *basis functions* on spin.

9.3.5 Numerical Atoms and Basis functions

The program starts with a calculation of the free atoms, assuming spherical symmetry. The formation energy is calculated w.r.t such atoms. You have to specify the configuration (i.e. which orbitals are occupied) in the Dirac subkey of the block key AtomType, and you can for instance use the experimental configuration. Keep in mind, however, that this is not necessarily the optimal configuration for your density functional. For instance, Ni has experimentally two electrons in the 4s shell, but with LDA you will find that it is energetically more profitable to move one electron from the 4s to the 3d. The configuration of the reference atoms does not (i.e. should not) affect the final (SCF) density.

Besides the available basis sets in $AMSHOME/atomicdata/band, you could in principle use the basis functions from the database of the molecular ADF program (see the documentation of ADF for how this database is organized). The functions you will find there are STOs, which is not optimal since BAND offers you the option to use NOs from the numerical atom. The most efficient approach is to use the NOs and remove from the ADF basis set those STOs that are already well described by the NOs.

As an example we will construct a basis for the Ni atom with orbitals frozen up to the *2p* shell, derived from a triple-zeta ADF basis. In the Dirac subkey of the block key AtomType you specify that the NOs up to *2p* should be kept frozen and that the 3d and *4s* NOs be included in the valence basis. Copy from the ADF database all *3d*, *4s* and the polarization functions into the BasisFunctions subkey of the block key AtomType and remove the middle STOs of the *3d* and the *4s*.

Usually it is already quite adequate for a good-quality basis to augment each NO with one STO. You could then take a double zeta ADF basis and remove one of the 3d and one of the 4s STOs. We often find that such a basis, with one STO

added per NO, has a quality that is comparable to *triple* zeta STO sets. We strongly recommend that you use combined NO/STO bases. Of course, you may want to verify the quality of the basis set by calculations on a few simple systems.

9.4 Warnings

9.4.1 Warnings specific to periodic codes (BAND, DFTB)

WARNING: GUESS: INPUT LATTICE MAY BE INACCURATE

WARNING: KSPACE ONLY GAMMA POINT.

WARNING: LINEAR INTEGRATION IN K-SPACE

WARNING: Problem with Brillouin zone k-path generation (see output file)

WARNING: problematic mapping to central cell

WARNING: QUAD2: electronic temperature problem

EXAMPLES

10.1 Introduction

The ADF package contains a series of sample runs for the BAND program. Provided are UNIX scripts to run the calculations and the resulting output files.

The examples serve:

- To check that the program has been installed correctly: run the sample inputs and compare the results with the provided outputs. *Read the remarks below about such comparisons.*

- To demonstrate how to do calculations: an illustration to the User manuals. The number of options available in BAND is substantial and the sample runs do not cover all of them. They should be sufficient, however, to get a feeling for how to explore the possibilities.

- To work out special applications that do not fit well in the User's Guide.

Where references are made to the operating system (OS) and to the file system on your computer the terminology of UNIX type OSs is used.

All sample files are stored in subdirectories under $AMSHOME/examples/, where $AMSHOME is the main directory of the ADF package. The main subdirectory for the BAND examples is $AMSHOME/examples/band. Each sample run has its own directory. For instance, $AMSHOME/examples/band/NaCl/ contains a BAND calculation on the NaCl bulk crystal. Each sample subdirectory contains:

- A file TestName.run: the UNIX script to execute the calculation or sequence of calculations of the example

- A file TestName_orig.out: the resulting output(s) against which you can compare the outcome of your own calculation.

Notes:

- Running the examples on Windows: You can run an example calculation by double-clicking on the appropriate .run file. After the calculation has finished, you can compare the TestName.out file with the reference Test-Name_orig.out file. See remarks about comparing output files below.

- The UNIX scripts make use of the *rm* (remove) command. Some UNIX users may have aliased the *rm* command. They should accordingly adapt these commands in the sample scripts so as to make sure that the scripts will remove the files. New users may get stuck initially because of files that are lingering around after an earlier attempt to run one of the examples. In a subsequent run, when the program tries to open a similar (temporary or result) file again, an error may occur if such a file already exists. Always make sure that no files are left in the run-directory except those that are required specifically.

- It is a good idea to run each example in a separate directory that contains no other important files.

- The run-scripts use the environment variables AMSBIN and AMSRESOURCES. They stand respectively for the directory that contains the program executables and the main directory of the database. To use the scripts as they

are you must have defined the variables AMSBIN and AMSRESOURCES in your environment. If a parallel version has been installed, it is preferable to have also the environment variable NSCM. This defines the default number of parallel processes that the program will try to use. Consult the Installation Manual for details.

- As you will note the sample run scripts refer to the programs by names like 'adf', 'band', and so on. When you inspect your $AMSBIN directory, however, you may find that the program executables have names 'adf.exe', 'band.exe'. There are also files in $AMSBIN with names 'adf', 'band', but these are in fact scripts to execute the binaries. We strongly recommend that you use these scripts in your calculations, in particular when running parallel jobs: the scripts take care of some aspects that you have to do otherwise yourself in each calculation.

- You need a license file to run any calculations successfully. If you have troubles with your license file, consult the Installation manual. If that doesn't help contact us at support@scm.com

Many of the provided samples have been devised to be short and simple, at the expense of physical or chemical relevance and precision or general quality of results. They serve primarily to illustrate the use of input, necessary files, and type of results. The descriptions have been kept brief. Extensive information about using keywords in input and their implications is given in the User's Guide and the Utilities and Property Programs documents (NMR, DIRAC, and other utility programs).

When you compare your own results with the sample outputs, you should check in particular (as far as applicable):

- Occupation numbers and energies of the one-electron orbitals;

- The optimized geometry;

- Vibrational frequencies;

- The bonding energy and the various terms in which it has been decomposed;

- The dipole moment;

- The logfile. At the end of a calculation the logfile is automatically appended (by the program itself) to the standard output.

General remarks about comparisons:

- For technical reasons, discussion of which is beyond the scope of this document, differences between results obtained on different machines, or with different numbers of parallel processes, may be much larger than you would expect. They may significantly exceed the machine precision. What you should check is that they fall well (by at least an order of magnitude) within the *numerical integration* precision used in the calculation.

- For similar reasons the orientation of the molecule used by the program may be different on different machines, even when the same input is supplied. In such cases the different orientations should be related and only differ in some trivial way, such as by a simple rotation of all coordinates by 90 degrees around the z-axis. When in doubt, contact an ADF representative.

- A BAND run may generate, apart from result files that you may want to save, a few scratch files. The UNIX scripts that run the samples take care of removing these files after the calculations have finished, to avoid that the program aborts in the next run by attempting to open a 'new' file that is found to exist already.

- A sample calculation may use one or more data files, in particular *fragment* files. The samples are self-contained: they first run the necessary pre-calculations to produce the fragment files. In 'normal' research work you may have libraries of fragments available, first for the 'basic atoms', and later, as projects are developing, also for larger fragments so that you can start immediately on the actual system by attaching the appropriate fragment files.

Default settings of print options result in a considerable amount of output. This is also the case in some of the sample runs, although in many of them quite a bit of 'standard' output is suppressed by inserting applicable print control keys in the input file. Consult the User's Guide about how to regulate input with keys in the input file.

10.2 Model Hamiltonians

10.2.1 Example: Spin polarization: antiferromagnetic iron

Download BetaIron.run

```sh
#! /bin/sh

# By setting 'Unrestricted Yes' we do a spin polarized calculation. Normally
# this would converge to the ferromagnetic solution.

# With the SpinFlipRegion keyword we make sure that we start with an antiferromagnetic
# density.

# For antiferromagnetic iron we need a larger unit cell of two atoms. Since
# these atoms appear to the program as symmetry equivalent we have to specify
# them as separate types.

10.2.9 Example: Hubbard combined with spin flip

The Hubbard model can be combined with spin flip. The toy system consists of two Cr atoms and two H atoms, the spin is flipped on one of the Cr atoms.

In this example it is shown how to achieve the same using three different input methods, of which the first (atom) is almost always the most convenient.

Download HubbardInputOptions.run

```bash
#!/bin/bash

report=report.txt

print_header() {
   echo "* This is a fairly advanced application of the Hubbard model"
   echo "* The toy model is a Cr dimer surrounded by two H atoms"
   echo "* It is a spin polarized calculation with the spin is flipped on one of the
→Cr atoms"
   echo "* The d orbitals of the two Cr atoms get a Hubbard U correction"
   echo "* Three equivalent input setups are shown to achieve the same"
   echo "* In the output feedback is given after the header: H U B B A R D   S E T T
→I N G S"

   printf "\n%10s %10s %10s\n" "input" "Energy" "E(hubbard)"
}

10.3.3 Example: Multiresolution

Download Multiresolution_H2O.run

```
#! /bin/sh

# This example demonstrates how to use different levels of numerical precision
# for different regions, with the aim of increasing computational efficiency.

# Let us assume that we are interested in having an accurate description only
# for a subregion of a large chemical system (in this simple example, the
# central water molecule). The system can be divided into sub-regions and
# different levels of numerical accuracy can be used for each of these sub-
# regions.

# In this example we will tweak:
# - the basis set (Basis)
# - the numerical integration (BeckeGrid)
# - the density fitting for Coulomb potential (ZlmFit)
# - the fit-set used in the Hartree-Fock Resolution of identity (RIHartreeFock)

# Note: For the regions for which no quality has been explicitly defined
# through a QualityPerRegion keyword, the quality defined in NumericalQuality
# will be used (Normal, in this example).

10.3.5 Example: Speed up SCF during geometry optimization

Generally the SCF converges more quickly when using a finite electronic temperature.

In this example it is shown (for a toy system that does not need the trick) how this can be done.

The report shows how the value of kT varies during a geometry optimization.

`Download report BandAutomations.txt`

```
We use a gradient dependent KT value (finite electronic temperature)

The value of kT gets progressively lower during the optimization

For two optimizers we do 3 steps and they do not converge. Yet the last single point␣
→should be done at KTlow=0.001

kT series for optimizer: Quasi-Newton
0.010000
0.007196
0.005094
0.002040
0.001000
0.001000
(the last kT should be 0.001)

scf converge serie for optimizer: Quasi-Newton
1.0E-03
1.0E-06
1.0E-06

1.0E-03
1.0E-06
1.0E-06
1.0E-06
1.0E-06
1.0E-06
```

`Download BandAutomations.run`

```bash
#!/bin/bash
```

```
# the System is extremely artificial but the calculation points out something useful

# The system has two CO molecules, one of which is compressed.
# We freeze the coordinates of the compressed CO molecules

# We define a gradient dependent electronic temperature (excluding the gradient of␣
↪the constrained atoms)
# When far from convergence a higher value is used to ease SCF convergence (not␣
↪relevant to this system)
# When the gradients become small the temperature is lowered, so that is will have␣
↪negligible influence on the energy

# Here we let on purpose not converge the geometry optimization
# The final calculation should be performed as a normal single point and we␣
↪explicitly set in band the ElectronicTemperature to 0.001

10.4 GTO

10.4.1 Example: eigenvalue-only self-consistent GW@PBE calculation: Ne with GTO type basis set

Download GW_Ne_GTO.run

```sh
#! /bin/sh

# GW calculation for Water. By default. The highest 5 occupied and lowest 5
# unoccupied states are calculated.

# We use an all-electron basis set since core-correlation effects are important.
# A large basis set is recommended for relatively well converged QP energies.
# With the 5Z GTO type basis set, we expect the QP energies to be converged
# within 0.1 eV.

# Fot this example we will use the GGA PBE.
# This is NOT a recommended starting point for a G0W0 calculation.
# However, the eigenvalue-only self-consistency removes most of the
# starting point dependence of the functional.
# Thererfore, PBE is a reasonable choice.

# RECOMMENDED: VeryGood numerical quality,
# especially in self-consistent GW calculations.

# We calculate the auxiliary fit set from products of primary basis functions.
# When the primary basis contains functions with angular momenta of l=5, like
# the cc-pV5Z one, we need functions in the fit with angular momenta of l=10.
# Building the auxiliary basis from fit funtions ensures this.

10.5.4 Example: DOS and BandStructure from a previous calculation

It is quite likely that you did a calculation, but forgot to request the DOS or BandStructure. Or maybe you did but want to use different settings.

Fortunately it is possible to calculate these directly from the previous calculation. The traditional way was to restart the SCF, but this is no longer needed.

With the restart of the DOS it has become possible to calculate the DOS with a finer k-space sampling. In this example it is shown that the DOS calculated this way matches well the DOS obtained from a full calculation with a dense k-grid (for both the SCF and DOS).

The example below features some concepts

- use environment variables to control in one place repeated settings

- DOS calculated on a fixed grid. This is not really needed, but it makes the comparison between different DOS results much more stable.

- `KSpace%Regular%DoubleCount` key. Useful when you want to check against a k-grid that is twice as dense.

- A text report is created, useful for automatic testing.

- –delete-old-results. Allow ams to overwrite an existing results folder.

Download RestartDosAndBandStructure.run

10.6 NEGF

10.6.1 Example: Main NEGF flavors

Download NEGF_Cr_wire.run

```
#! /bin/sh

# This example shows how to use the NEGF functionality.
# Note: Setting up a NEGF calculation is quite hard without the GUI.

# It starts of with Method 1: the non-self consistent approach. Here, BAND
# merely serves to provide matrix elements, being unaware of the electrodes.

# Then follows Method 2: here the NEGF density is really used to calculate the
# matrix elements.

# Method 3 is a variation on Method 2, and includes an extra alignment run.

# ============================================================================
#  Method #1: non-self consistent NEGF (uses the conductance program, like DFTB)
# ============================================================================

# ======================= Method #1. Run #1   ============================

10.7 Structure and Reactivity

10.7.1 Example: NaCl: Bulk Crystal

Download NaCl.run

```
#! /bin/sh

# A bulk crystal computation for Sodium Chloride (common salt), with a
# subsequent DOS analysis, using a Restart facility to use the results from a
# preceding calculation.

# The BAND input follows slightly different conventions from the ADF input, for
# historical reasons.

# Since there are 3 data records in the Lattice block, the calculation will
# assume 3-dimensional periodicity, with lattice vectors as indicated. Note that
# lattice vectors are undefined up to linear combinations among themselves.
# Internally, the program will recombine the input vectors so as to minimize the
# size of the actually used vectors.

# The input line FractionalCoords True means that atomic positions are input as
# coefficients in terms of the lattice vectors, rather than as absolute
# (Cartesian) coordinate values.

10.8 Time dependent DFT

10.8.1 Example: TD-CDFT for MoS2 Monolayer (NewResponse)

Download NewResp_2DMoS2Restart.run

```
#!/bin/sh

# This example demonstrates how to calculate the frequency-dependent dielectric
# function with the help of the NewResponse implementation for a two-dimensional
# system. (see NewResponse) Furthermore, the general setup to run the TD-CDFT
# section as a restart calculation is presented as well. This allows for
# splitting of the frequency range into several parts, which can then be
# calculated in separate calculation without the overhead of evaluating the
# groundstate properties for each of them! Hence, it is a trivial
# parallelization possibility.

10.10 GW

10.10.1 Example: eigenvalue-only self-consistent GW@PBE calculation: H2O

Download GW_H2O.run

```sh
#! /bin/sh

# GW calculation for Water. By default. The highest 5 occupied and lowest 5
# unoccupied states are calculated.

# We use an all-electron basis set since core-correlation effects are important.
# A QZ basis set is recommended for relatively converged QP energies

# Fot this example we will use the GGA PBE.
# This is NOT a recommended starting point for a G0W0 calculation.
# However, the eigenvalue-only self-consistency removes most of the #
# starting point dependence of the functional.
# Thererfore, PBE is a reasonable choice.

# RECOMMENDED: VeryGood numerical quality,
# especially in self-consistent GW calculations.

10.11 Analysis

10.11.1 Example: CO absorption on a Cu slab: fragment option and densityplot

Download Frags_COCu.run

```sh
#! /bin/sh

# This example illustrates the usage of fragments in a BAND calculation for
# analysis purposes. It takes two runs to do the DOS analysis in a fragment
# basis, and an extra two runs to get the deformation density with respect to
# the fragment densities.

# The setup involves first the computation of the free CO overlayer, which is to
# be adsorbed on a Cu surface. To suppress (most of the) interactions between
# the CO molecules, i.e. to effectively get the molecular CO, the KSpace
# parameter is set to 1 (= no dispersion), and the lattice parameters are set so
# large that the CO molecules are far apart. The standard result file RUNKF is
# saved under the name 'CO.results/band.rkf'.

# --------------------------- CO molecule --------------------------

# In the output file the results can be found in the PEDANOCV block after the
# Energy Analysis and PEDA block.

# The NOCV orbitals and NOCV deformation densities can be visualized using
# AMSview or by a restart calculation. In the latter case, one adds the Restart
# block key with the options File decomp.kf and the NOCVdRhoPlot and
# NOCVOrbitalPlot keys. These will trigger the calculation of the plot
# properties. To specify which NOCV deformation densities and NOCV orbitals are
# plotted, one adds the NOCVdRhoPlot and NOCVOrbitalPlot block key. In both
# blocks the line 1 Band 1 5 means, that for k-point 1 the densities/orbitals 1
# to 5 are calculated.

10.12 List of Examples

REQUIRED CITATIONS

When you publish results in the scientific literature which were obtained with programs of the ADF package, you are required to include references to the program package with the appropriate release number, and a few key publications.

In addition references to special features are mandatory, in case you have used them.

11.1 General References

For calculations with the periodic structures BAND program, version 2020.1:

1. G. te Velde and E.J. Baerends, *Precise density-functional method for periodic structures*, Physical Review B 44, 7888 (1991) (https://doi.org/10.1103/PhysRevB.44.7888).

2. BAND 2024.1, SCM, Theoretical Chemistry, Vrije Universiteit, Amsterdam, The Netherlands, http://www.scm. com Optionally, you may add the following list of authors and contributors: P.H.T. Philipsen, G. te Velde, E.J. Baerends, J.A. Berger, P.L. de Boeij, M. Franchini, J.A. Groeneveld, E.S. Kadantsev, R. Klooster, F. Kootstra, M.C.W.M. Pols, P. Romaniello, M. Raupach, D.G. Skachkov, J.G. Snijders, C.J.O. Verzijl, J.A. Celis Gil, J. M. Thijssen, G. Wiesenekker, C. A. Peeples, G. Schreckenbach, T. Ziegler.

Note: if you have used a modified (by yourself, for instance) version of the code, you should mention in the citation that a modified version has been used.

11.2 Feature References

12.2 Summary of all keywords

12.2.1 Engine Band

AIMCriticalPoints

> **Type** Block
>
> **Description** Compute the critical points of the density (Atoms In Molecules). The algorithm starts from a regular mesh of points, and from each of these it walks towards its corresponding critical point.

Enabled

> **Type** Bool
>
> **Default value** No
>
> **GUI name** : Critical points and bond paths
>
> **Description** Compute the critical points of the density (Atoms In Molecules). The algorithm starts from a regular mesh of points, and from each of these it walks towards its corresponding critical point.

EqvPointsTol

> **Type** Float
>
> **Default value** 0.27
>
> **Unit** Bohr
>
> **Description** If the distance between two critical points is smaller than this value, the two critical points are considered to be the same point.

GridPadding

> **Type** Float
>
> **Default value** 0.7
>
> **Unit** Bohr
>
> **Description** How much extra space is added to the starting guess domain in the search for the critical points

GridSpacing

> **Type** Float
>
> **Default value** 0.5
>
> **Unit** Bohr
>
> **Description** The distance between the initial trial points.

Allow

> **Type** String

Recurring True

Description Debugging feature to let the program continue even when intermediate results seem to be wrong or very inaccurate

ATensor

> **Type** Block

> **Description** Hyperfine A-tensor.

> **Enabled**

>> **Type** Bool

>> **Default value** No

>> **GUI name** :A-tensor

>> **Description** Compute the hyperfine A-tensor.

>>> Note: Unrestricted calculation is required.

AtomType

> **Type** Block

> **Recurring** True

> **Description** Explicit basis set definition for given atom type.

> **AutomaticGaussians**

>> **Type** Non-standard block

>> **Description** Definition of the automatic gaussians

> **BasisFunctions**

>> **Type** Non-standard block

>> **Description** Definition of the extra Slater-type orbitals

> **ContractedGaussians**

>> **Type** Non-standard block

>> **Description** Definition of the contracted gaussians

> **Dirac**

>> **Type** Non-standard block

>> **Description** Specification of the numerical ('Herman-Skillman') free atom, which defines the initial guess for the SCF density, and which also (optionally) supplies Numerical Atomic Orbitals (NOs) as basis functions

> **FitFunctions**

>> **Type** Non-standard block

>> **Description** Slater-type fit functions. Obsolete feature.

BandStructure

> **Type** Block

> **Description** Options for the calculation of the band structure.

> **Automatic**

Type Bool

Default value Yes

GUI name Automatic generate path

Description If True, BAND will automatically generate the standard path through the Brillouin zone.

If False BAND will use the user-defined path in BZPath.

DeltaK

Type Float

Default value 0.1

Unit 1/Bohr

GUI name Interpolation delta-K

Description Step (in reciprocal space) for band structure interpolation.

Using a smaller number (e.g. 0.03) will result in smoother band curves at the cost of an increased computation time.

Enabled

Type Bool

Default value No

GUI name Calculate band structure

Description If True, Band will calculate the band structure and save it to file for visualization.

EnergyAboveFermi

Type Float

Default value 0.75

Unit Hartree

GUI name Energy above Fermi level

Description Bands with minimum energy larger then FermiEnergy + EnergyAboveFermi are not saved to file. Increasing the value of EnergyAboveFermi will result in more unoccupied bands to be saved to file for visualization.

EnergyBelowFermi

Type Float

Default value 10.0

Unit Hartree

GUI name Energy below Fermi level

Description Bands with maximum energy smaller then FermiEnergy - EnergyBelowFermi are not saved to file. Increasing the value of EnergyBelowFermi will result in more occupied core bands to be saved to file for visualization. Note: EnergyBelowFermi should be a positive number!

FatBands

Type Bool

Default value Yes

GUI name Calculate fatbands

Description If True, BAND will compute the fat bands (only if BandStructure%Enabled is True).

The Fat Bands are the periodic equivalent of the Mulliken population analysis.

UseSymmetry

Type Bool

Default value Yes

GUI name Use symmetry

Description If True, only the irreducible wedge of the Wigner-Seitz cell is sampled.

If False, the whole (inversion-unique) Wigner-Seitz cell is sampled.

Note: The Symmetry key does not influence the symmetry of the band structure sampling.

Basis

Type Block

Description Definition of the basis set

Core

Type Multiple Choice

Default value Large

Options [None, Small, Medium, Large]

GUI name Frozen core

Description Select the size of the frozen core you want to use.

Small, Medium, and Large will be interpreted within the basis sets available (of the selected quality), and might refer to the same core in some cases.

Folder

Type String

Description Path to a folder containing the basis set files. This can be used for special use-defined basis sets. Cannot be used in combination with 'Type'

PerAtomType

Type Block

Recurring True

Description Defines the basis set for all atoms of a particular type.

Core

Type Multiple Choice

Options [None, Small, Medium, Large]

Description Size of the frozen core.

File

Type String

> **Description** The path to the basis set file. The path can be absolute or relative to $AMSRE-SOURCES/Band. Specifying the path to the basis file explicitly overrides the automatic basis file selection via the Type and Core subkeys.

Symbol

> **Type** String
>
> **Description** The symbol for which to define the basis set.

Type

> **Type** Multiple Choice
>
> **Options** [SZ, DZ, DZP, TZP, TZ2P, QZ4P]
>
> **Description** The basis sets to be used.

PerRegion

> **Type** Block
>
> **Recurring** True
>
> **Description** Defines the basis set for all atoms in a region. If specified, this overwrites the values set with the Basis%Type and Basis%PerAtomType keywords for atoms in that region. Note that if this keyword is used multiple times, the chosen regions may not overlap.

Core

> **Type** Multiple Choice
>
> **Default value** Large
>
> **Options** [None, Small, Medium, Large]
>
> **Description** Size of the frozen core.

Region

> **Type** String
>
> **Description** The identifier of the region for which to define the basis set. Note that this may also be a region expression, e.g. 'myregion+myotherregion' (the union of two regions).

Type

> **Type** Multiple Choice
>
> **Default value** DZ
>
> **Options** [SZ, DZ, DZP, TZP, TZ2P, QZ4P]
>
> **Description** The basis sets to be used.

Type

> **Type** Multiple Choice
>
> **Default value** DZ
>
> **Options** [SZ, DZ, DZP, TZP, TZ2P, QZ4P, STO/TZ2P, STO/SZ, STO/DZ, STO/DZP, STO/QZ4P, CORR/QZ6P, CORR/TZ3P, GTO/CC-PV5Z, GTO/DEF2-QZVPPD, GTO/CC-PV6Z, GTO/CC-PVQZ, GTO/CC-PVTZ, GTO/CC-PVDZ, GTO/DEF2-SVP, GTO/DEF2-TZVP, GTO/DEF2-TZVPP, GTO/DEF2-QZVP, GTO/AUG-CC-PVDZ, GTO/AUG-CC-PVTZ]
>
> **GUI name** Basis set

Description Select the basis set to use.

SZ : Single Z DZ : Double Z DZP : Double Z, 1 polarization function TZP : Triple Z, 1 polarization function TZ2P : Triple Z, 2 polarization functions QZ4P : Quadruple Z, 4 polarization function

The basis set chosen will apply to all atoms in your structure. If a matching basis is not found a better type might be used.

BeckeGrid

> **Type** Block
>
> **Description** Options for the numerical integration grid, which is a refined version of the fuzzy cells integration scheme developed by Becke.
>
> **Quality**
>
> > **Type** Multiple Choice
> >
> > **Default value** Auto
> >
> > **Options** [Auto, Basic, Normal, Good, VeryGood, Excellent]
> >
> > **Description** Quality of the integration grid. For a description of the various qualities and the associated numerical accuracy see reference. If 'Auto', the quality defined in the 'NumericalQuality' will be used.
>
> **QualityPerRegion**
>
> > **Type** Block
> >
> > **Recurring** True
> >
> > **Description** Sets the grid quality for all atoms in a region. If specified, this overwrites the globally set quality.
> >
> > **Quality**
> >
> > > **Type** Multiple Choice
> > >
> > > **Options** [Basic, Normal, Good, VeryGood, Excellent]
> > >
> > > **Description** The region's integration grid quality.
> >
> > **Region**
> >
> > > **Type** String
> > >
> > > **Description** The identifier of the region for which to set the quality.
>
> **RadialGridBoost**
>
> > **Type** Float
> >
> > **Default value** 1.0
> >
> > **Description** The number of radial grid points will be boosted by this factor. Some XC functionals require very accurate radial integration grids, so BAND will automatically boost the radial grid by a factor 3 for the following numerically sensitive functionals: LibXC M05, LibXC M05-2X, LibXC M06-2X, LibXC M06-HF, LibXC M06-L, LibXC M08-HX, LibXC M08-SO, LibXC M11-L, LibXC MS0, LibXC MS1, LibXC MS2, LibXC MS2H, LibXC MVS, LibXC MVSH, LibXC N12, LibXC N12-SX, LibXC SOGGA11, LibXC SOGGA11-X, LibXC TH1, LibXC TH2, LibXC WB97, LibXC WB97X, MetaGGA M06L, MetaHybrid M06-2X, MetaHybrid M06-HF, MetaGGA MVS.

BerryPhase

Type Bool

Default value No

Description Boolean that determines whether the dipole as determined through the Berry phase approach should be calculated.

BField

Type Block

Description The effect of a magnetic filed can be approximated by the following potential: mu * sigma_i * B, where mu is the Bohr magneton, sigma_i are the Pauli matrices and B is the magnetic field

Bx

Type Float

Default value 0.0

Unit Tesla

Description Value of the x component of the BField

By

Type Float

Default value 0.0

Unit Tesla

Description Value of the y component of the BField

Bz

Type Float

Default value 0.0

Unit Tesla

Description Value of the z component of the BField

Dipole

Type Bool

Default value No

GUI name Bfield is: Atomic dipole

Description Use an atomic dipole as magnetic field instead of a uniform magnetic field.

DipoleAtom

Type Integer

Default value 1

GUI name on atom number

Description Atom on which the magnetic dipole should be centered (if using the dipole option)

Method

Type Multiple Choice

Default value NR_SDOTB

Options [NR_SDOTB, NR_LDOTB, NR_SDOTB_LDOTB]

Description There are two terms coupling to an external magnetic field.

One is the intrinsic spin of the electron, called S-dot-B, the other one is the orbital momentum call L-dot-B.

The L.B is implemented non-relativistically, using GIAOs in the case of a homogeneous magnetic field (not for the dipole case).

Unit

Type Multiple Choice

Default value tesla

Options [tesla, a.u.]

Description Unit of magnetic filed. The a.u. is the SI version of a.u.

BZPath

Type Block

Description Definition of the user-defined path in the Brillouin zone for band structure plotting.

path

Type Non-standard block

Recurring True

Description Definition of the k-points in a path. The vertices of your path should be defined in fractional coordinates (wrt the reciprocal lattice vectors)

Comment

Type Non-standard block

Description The content of this block will be copied to the output header as a comment to the calculation.

Convergence

Type Block

Description Options and parameters related to the convergence behavior of the SCF procedure.

Criterion

Type Float

Description Criterion for termination of the SCF procedure. The default depends on the NumericalQuality and on the number of atoms in the system. Can be used for EngineAutomations

CriterionFactor

Type Float

Default value 1.0

Description Multiply Criterion (which depends on system and quality) with this factor. Can be used for EngineAutomations

Degenerate

Type String

Default value default

Description Smooths (slightly) occupation numbers around the Fermi level, so as to insure that nearly-degenerate states get (nearly-) identical occupations. Be aware: In case of problematic SCF convergence the program will turn this key on automatically, unless the key 'Nodegenerate' is set in input. The smoothing depends on the argument to this key, which can be considered a 'degeneration width'. When the argument reads default, the program will use the value 1e-4 a.u. for the energy width.

ElectronicTemperature

    Type Float

    Default value 0.0

    Unit Hartree

    Description (KT) Specify this key for a gradient independent electronic temperature

InitialDensity

    Type Multiple Choice

    Default value rho

    Options [rho, psi, frompot]

    Description The SCF is started with a guess of the density. There are the following choices RHO: the sum of atomic density. PSI: construct an initial eigensystem by occupying the atomic orbitals. The guessed eigensystem is orthonormalized, and from this the density is calculated/

LessDegenerate

    Type Bool

    Default value No

    Description If smoothing of occupations over nearly degenerate orbitals is applied (see Degenerate key), then, if this key is set in the input file, the program will limit the smoothing energy range to 1e-4 a.u. as soon as the SCF has converged 'halfway', i.e. when the SCF error has decreased to the square root of its convergence criterion.

ModestCriterion

    Type Float

    Default value -1.0

    Description If this is specified band will consider the SCF converged if the error is below this criterion (after using the maximum number of iterations).

NoDegenerate

    Type Bool

    Default value No

    Description This key prevents any internal automatic setting of the key DEGENERATE.

NumBoltz

    Type Integer

    Default value 10

    Description The electronic temperature is done with a Riemann Stieltjes numerical integration, between zero and one occupation. This defines the number of points to be used.

SpinFlip

Type Integer List

GUI name Flip spin for atoms

Description List here the atoms for which you want the initial spin polarization to be flipped. This way you can distinguish between ferromagnetic and anti ferromagnetic states. Currently, it is not allowed to give symmetry equivalent atoms a different spin orientation. To achieve that you have to break the symmetry.

SpinFlipEnabled

    Type Bool

    Default value Yes

    Description If set to False, the keys SpinFlip and SpinFlipRegion are ignored. Only useful/convenient when trying to compare in a script the effect of spin flip.

SpinFlipRegion

    Type String

    Recurring True

    GUI name Flip spin for region

    Description Specify here the region for which you want the initial spin polarization to be flipped. This way you can distinguish between ferromagnetic and anti ferromagnetic states. Currently, it is not allowed to give symmetry equivalent atoms a different spin orientation. To achieve that you have to break the symmetry.

StartWithMaxSpin

    Type Bool

    Default value Yes

    Description To break the initial perfect symmetry of up and down densities there are two strategies. One is to occupy the numerical orbitals in a maximum spin configuration. The alternative is to add a constant to the potential. See also Vsplit key.

StartWithMaxSpinForSO

    Type Bool

    Default value No

    Description Same as the StartWithMaxSpin option. In case of spin-orbit band always used to split the potential. Now will use maxspin in case of SpinFlip. With this option it will always do that.

CPVector

    Type Integer

    Default value 128

    GUI name Vectorlength (blocksize)

    Description The code is vectorized and this key can be used to set the vector length

DensityPlot

    Type Non-standard block

    Description Plots of the density. Goes together with the Restart%DensityPlot and Grid keys.

Dependency

Type Block

Description Criteria for linear dependency of the basis and fit set

AllowBasisDependency

> **Type** Bool
>
> **Default value** Yes
>
> **Description** Project out the dependent part of the basis set (associated with small eigenvalues of the overlap matrix).

Basis

> **Type** Float
>
> **Default value** 1e-08
>
> **GUI name** Dependency criterion
>
> **Description** Criteria for linear dependency of the basis: smallest eigenvalue of the overlap matrix of normalized Bloch functions.

Core

> **Type** Float
>
> **Default value** 0.8
>
> **Description** The program verifies that the frozen core approximation is reasonable, by checking the smallest eigen value of the overlap matrix of the core (Bloch) orbitals (which should ideally be one) is bigger than this criterion.

CoreValence

> **Type** Float
>
> **Default value** 1e-05
>
> **Description** Criterion for dependency of the core functions on the valence basis. The maximum overlap between any two normalized functions in the two respective function spaces should not exceed 1.0-corevalence

Fit

> **Type** Float
>
> **Default value** 5e-06
>
> **Description** Criterion for dependency of the total set of fit functions. The value monitored is the smallest eigenvalue of the overlap matrix of normalized Bloch sums of symmetrized fit functions.

DIIS

Type Block

Description Parameters for the DIIS procedure to obtain the SCF solution

Adaptable

> **Type** Bool
>
> **Default value** Yes
>
> **Description** Change automatically the value of dimix during the SCF.

CHuge

>   **Type** Float

>   **Default value** 20.0

>   **GUI name** No DIIS (but damping) when coefs >

>   **Description** When the largest coefficient in the DIIS expansion exceeds this value, damping is
>   applied

CLarge

>   **Type** Float

>   **Default value** 20.0

>   **GUI name** Reduce DIIS space when coefs >

>   **Description** When the largest DIIS coefficient exceeds this value, the oldest DIIS vector is removed
>   and the procedure re-applied

Condition

>   **Type** Float

>   **Default value** 1000000.0

>   **Description** The condition number of the DIIS matrix, the largest eigenvalue divided by the small-
>   est, must not exceed this value. If this value is exceeded, this vector will be removed.

DiMix

>   **Type** Float

>   **Default value** 0.2

>   **GUI name** Bias DIIS towards latest vector with

>   **Description** Mixing parameter for the DIIS procedure

DiMixMax

>   **Type** Float

>   **Default value** -1.0

>   **Description** For adaptive diis: A negative value means automatic, see DiMixatnvctrx. If positive
>   it is an absolute upper bound for (adaptive) dimix

DiMixMin

>   **Type** Float

>   **Default value** 0.01

>   **Description** An absolute lower bound for adaptive dimix.

NCycleDamp

>   **Type** Integer

>   **Default value** 1

>   **GUI name** Do not start DIIS before cycle

>   **Description** Number of initial iterations where damping is applied, before any DIIS is considered

NVctrx

>   **Type** Integer

Default value 20

GUI name Size of DIIS space

Description Maximum number of DIIS expansion vectors

Variant

> **Type** Multiple Choice
>
> **Default value** DIIS
>
> **Options** [DIIS, LISTi, LISTb, LISTd]
>
> **Description** Which variant to use. In case of problematic SCF convergence, first try MultiSecant, and if that does not work the LISTi is the advised method. Note: LIST is computationally more expensive per SCF iteration than DIIS.

DOS

> **Type** Block
>
> **Description** Density-Of-States (DOS) options

CalcDOS

> **Type** Bool
>
> **Default value** Yes
>
> **GUI name** Calculate DOS
>
> **Description** Whether or not to calculate the density of states.

CalcPDOS

> **Type** Bool
>
> **Default value** No
>
> **GUI name** Calculate PDOS
>
> **Description** Whether or not to calculate the partial DOS (projections on basis functions). This can be significantly more expensive than calculating the total DOS

CalcPopulationAnalysis

> **Type** Bool
>
> **Default value** Yes
>
> **GUI name** Calculate Mulliken charges
>
> **Description** Whether or not to calculate the population analysis. Population analysis can become very expensive when there are many symmetry operators, such as in a super cell.

CompensateDeltaE

> **Type** Bool
>
> **Default value** Yes
>
> **Description** Only relevant when IntegrateDeltaE=yes. If set to true then after integrating each interval over DeltaE the result is divided by DeltaE, so that the unit is DOS.

DeltaE

> **Type** Float
>
> **Default value** 0.005

Unit Hartree

GUI name Delta E

Description Energy step for the DOS grid. Using a smaller value (e.g. half the default value) will result in a finer sampling of the DOS.

Energies

Type Integer

Description Number of equidistant energy-values for the DOS grid. This keyword is superseded by the 'DeltaE' keyword.

File

Type String

Description Write the DOS (plain text format) to the specified file instead of writing it to the standard output.

IntegrateDeltaE

Type Bool

Default value Yes

Description This subkey handles which algorithm is used to calculate the data-points in the plotted DOS. If true, the data-points represent an integral over the states in an energy interval. Here, the energy interval depends on the number of Energies and the user-defined upper and lower energy for the calculation of the DOS. The result has as unit [number of states / (energy interval * unit cell)]. If false, the data-points do represent the number of states for a specific energy and the resulting plot is equal to the DOS per unit cell (unit: [1/energy]). Since the resulting plot can be a wild function and one might miss features of the DOS due to the step length between the energies, the default is set to the integration algorithm.

Max

Type Float

Unit Hartree

Description User defined upper bound energy (with respect to the Fermi energy)

Min

Type Float

Unit Hartree

Description User defined lower bound energy (with respect to the Fermi energy)

StoreCoopPerBasPair

Type Bool

Default value No

GUI name Calculate COOP

Description Calculate the COOP (crystal orbital overlap population).

DosBas

Type Non-standard block

Description Used to specify the fragment basis for the DOS.

DumpBasisOnly

>> **Type** Bool

>> **Default value** No

>> **Description** Dump basis and fit set files use for each atom.

EffectiveMass

>> **Type** Block

>> **Description** In a semi-conductor, the mobility of electrons and holes is related to the curvature of the bands at the top of the valence band and the bottom of the conduction band.

>> With the effective mass option, this curvature is obtained by numerical differentiation.

>> The estimation is done with the specified step size, and twice the specified step size, and both results are printed to give a hint on the accuracy. The easiest way to use this key is to enabled it without specifying any extra options.

> **Enabled**

>> **Type** Bool

>> **Default value** No

>> **GUI name** Effective mass

>> **Description** Compute the EffectiveMass.

> **KPointCoord**

>> **Type** Float List

>> **Unit** 1/Bohr

>> **Recurring** True

>> **GUI name** At K-point

>> **Description** Coordinate of the k-points for which you would like to compute the effective mass.

> **NumAbove**

>> **Type** Integer

>> **Default value** 1

>> **GUI name** Include N bands above

>> **Description** Number of bands to take into account above the Fermi level.

> **NumBelow**

>> **Type** Integer

>> **Default value** 1

>> **GUI name** Include N bands below

>> **Description** Number of bands to take into account below the Fermi level.

> **StepSize**

>> **Type** Float

>> **Default value** 0.001

>> **Description** Size of the step taken in reciprocal space to perform the numerical differentiation

EFG

>> **Type** Block

>> **Description** The electronic charge density causes an electric field, and the gradient of this field couples with the nuclear quadrupole moment, that some (non-spherical) nuclei have and can be measured by several spectroscopic techniques. The EFG tensor is the second derivative of the Coulomb potential at the nuclei. For each atom it is a 3x3 symmetric and traceless matrix. Diagonalization of this matrix gives three eigenvalues, which are usually ordered by their decreasing absolute size and denoted as V_{xx}, V_{yy}, V_{zz}. The result is summarized by the largest eigenvalue and the asymmetry parameter.

> **Enabled**

>> **Type** Bool

>> **Default value** No

>> **GUI name** EFG (electric field gradient): Calculate

>> **Description** Compute the EFG tensor (for nuclear quadrupole interaction).

EigThreshold

>> **Type** Float

>> **Default value** 0.01

>> **Description** Threshold for printing the eigenvectors coefficients (Print Eigens)

ElectronHole

>> **Type** Block

>> **Description** Allows one to specify an occupied band which shall be depopulated, where the electrons are then moved to the Fermi level. For a spin-restricted calculation 2 electrons are shifted and for a spin-unrestricted calculation only one electron is shifted.

> **BandIndex**

>> **Type** Integer

>> **Description** Which occupied band shall be depopulated.

> **SpinIndex**

>> **Type** Integer

>> **Description** Defines the spin of the shifted electron (1 or 2).

EmbeddingPotential

>> **Type** Block

>> **Description** An external potential can be read in and will be added to the effective Kohn-Sham potential. It has to be on the becke grid

> **Filename**

>> **Type** String

>> **Default value**

>> **Description** Name of the file containing the embedding potential.

> **PotentialName**

>> **Type** String

Default value

Description Name of variable containing the potential.

EnforcedSpinPolarization

Type Float

GUI name Spin polarization

Description Enforce a specific spin-polarization instead of occupying according to the aufbau principle. The spin-polarization is the difference between the number of alpha and beta electron.

Thus, a value of 1 means that there is one more alpha electron than beta electrons.

The number may be anything, including zero, which may be of interest when searching for a spin-flipped pair, that may otherwise end up in the (more stable) parallel solution.

ESR

Type Block

Description Zeeman g-tensor. The Zeeman g-tensor is implemented using two-component approach of Van Lenthe and co-workers in which the g-tensor is computed from a pair of spinors related to each other by time-reversal symmetry. Note: the following options are necessary for ESR: 'Relativistic zora spin' and 'Kspace 1'

Enabled

Type Bool

Default value No

GUI name ESR: g-tensor

Description Compute Zeeman g-tensor.

The Zeeman g-tensor is implemented using two-component approach of Van Lenthe and co-workers in which the g-tensor is computed from a pair of spinors related to each other by time-reversal symmetry.

Note: the following options are necessary for ESR: 'Relativistic zora spin' and 'Kspace 1'

Excitations

Type Block

Description Excitation energies: UV/Vis

Fermi

Type Block

Description Technical parameter used in determining the Fermi energy, which is carried out at each cycle of the SCF procedure.

Delta

Type Float

Default value 0.0001

Description Convergence criterion: upper and lower bounds for the Fermi energy and the corresponding integrated charge volumes must be equal within delta.

Eps

Type Float

Default value 1e-10

Description After convergence of the Fermi energy search procedure, a final estimate is defined by interpolation and the corresponding integrated charge volume is tested. It should be exact, to machine precision. Tested is that it deviates not more than eps.

MaxTry

Type Integer

Default value 15

Description Maximum number of attempts to locate the Fermi energy. The procedure is iterative in nature, narrowing the energy band in which the Fermi energy must lie, between an upper and a lower bound. If the procedure has not converged sufficiently within MaxTry iterations, the program takes a reasonable value and constructs the charge density by interpolation between the functions corresponding to the last used upper and lower bounds for the Fermi energy.

RefinePostSCFFactor

Type Integer

Description Use a finer k-grid after the scf to calculate a refined fermi level. Makes only sense for metals. Works like DoubleCount. Use 1,2,3

FermiSurface

Type Block

Description Calculation of the Fermi surface for metals

Enabled

Type Bool

Default value No

GUI name Calculate Fermi surface

Description Calculate the Fermi surface if the system has no band gap (i.e. is a metal). The result can be visualized with amsbands.

KIntegForSymmetricKGrid

Type Integer

Default value -1

Description If the (default) regular k-grid is used, a symmetric one is created to determine the Fermi surface. If this key is not specified an automatic value of kInteg is used. Odd values trigger quadratic interpolation.

NMesh

Type Integer

Default value 7

Description Improves the matching of the interpolated quadratic surface. For better results it makes more sense to increaes KIntegForSymmetricKGrid.

FormFactors

Type Integer

Default value 2

Description Number of stars of K-vectors for which the form factors are computed

Fragment

> **Type** Block
>
> **Recurring** True
>
> **Description** Defines a fragment. You can define several fragments for a calculation.

> **AtomMapping**
>
> > **Type** Non-standard block
> >
> > **Description** Format 'indexFragAt indexCurrentAt'. One has to associate the atoms of the fragment to the atoms of the current calculation. So, for each atom of the fragment the indexFragAt has to be associated uniquely to the indexCurrentAt for the current calculation.

> **Filename**
>
> > **Type** String
> >
> > **Description** Filename of the fragment. Absolute path or path relative to the executing directory.

> **Labels**
>
> > **Type** Non-standard block
> >
> > **Description** This gives the possibility to introduce labels for the fragment orbitals. See examples.

FuzzyPotential

> **Type** Non-standard block
>
> **Description** Atomic (fuzzy cell) based, external, electric potential. See example.

FuzzyUnitCellGrid

> **Type** Block
>
> **Description** Undocumented.

> **AtomRadiusLSG**
>
> > **Type** Float

>   >
>   >   **Options** [coarse, medium, fine]
>   >
>   >   **Description** The default regular grids.

>   **UserDefined**
>
>   >   **Type** Non-standard block
>   >
>   >   **Description** One can define the regular grid specification in this block. See example. Default unit is Bohr

GridBasedAIM

>   **Type** Block

> **Description** Invoke the ultra fast grid based Bader analysis.

Enabled

> **Type** Bool
>
> **Default value** No
>
> **GUI name** Bader (AIM): Atomic properties
>
> **Description** Invoke the ultra fast grid based Bader analysis.

Iterations

> **Type** Integer
>
> **Default value** 40
>
> **Description** The maximum number of steps that may be taken to find the nuclear attractor for a grid point.

SmallDensity

> **Type** Float
>
> **Default value** 1e-06
>
> **Description** Value below which the density is ignored. This should not be chosen too small because it may lead to unassignable grid points.

UseStartDensity

> **Type** Bool
>
> **Default value** No
>
> **Description** Whether the analysis is performed on the startup density (True) or on the final density (False).

GrossPopulations

> **Type** Non-standard block
>
> **Description** Partial DOS (pDOS) are generated for the gross populations listed under this key. See example.

GW

> **Type** Block
>
> **Description** Instruct ADF to perform a G0W0 calculation.

AdaptiveMixing

> **Type** Float List
>
> **Description** Requests to use adaptive mixing instead of DIIS and sets the staring mixing parameter for mixing of Green's function in case of self-consistency.
>
> Adapative mixing is recommenened in case a qsGW calculation does not converge with DIIS.
>
> It is ignored in non-selfconsistent calculation and overwritten by DIIS when DIIS is also present.

AnalyticalIntegration

> **Type** Block
>
> **Description** Use analytical integration to calculate the self-energy. Very slow, unless the system is very small but useful to check the accuracy of the frequency integration

Enabled

> **Type** Bool
>
> **Default value** No
>
> **GUI name** analytical integration
>
> **Description** Enable the calculation of the GW quasi-particle energies via analytical integration.

Polarizability

> **Type** Multiple Choice
>
> **Default value** RPA
>
> **Options** [RPA, BSE]
>
> **Description** Sets the expression for the Polarizability used in the GW calculation.
>
> RPA is the Default and amounts to a standard GW calculation.
>
> BSE denotes screening in the Bethe-Salpeter-equation formalism.

PrintSpectralFunction

> **Type** Bool
>
> **Default value** No
>
> **Description** Plot the self-energy as a function of freuency. Aotumatically done in case of analytical continuation. However, this is expensive in the analytical integration formalism.

SpectralFunctionResolution

> **Type** Integer
>
> **Default value** 800
>
> **Description** Number of points at which spectral function is evaluated.

TDA

> **Type** Bool
>
> **Default value** No
>
> **Description** Solve the linear reponse equations in the Tamm-Dancoff approximation.

eta

> **Type** Float
>
> **Default value** 0.001
>
> **Description** Artificial (positive) broadening parameter for evaluation of self-energy in analytical integration.
>
> Ideally should be as small as possible but this might lead to convergence issues in partially self-consistent approaches.
>
> In this case, a value of up to 0.1 is possible.

Converge

> **Type** Block
>
> **Description** Sets convergence criteria for the GW calculation in self-consistent case

Density

Type Float List

Default value [1e-08, 1e-05]

Description First Criterion for self-consistency procedure to terminate.

Criterion is the trace of the density matrix. Ignored in non-selfconsistent Calculation and in eigenvalue self-consistent GW

It is possible to run a qsGW calculation with an inner SCF loop which updates the static part of the elf-energy only. This can be useful to accelerate the convergence in case linear mixing is used. It is not recommended to use linear mixing, so it is also not recommened to use that inner loop as well. The second number in this list specifies the convergence criterion for the inner SCF loop.

HOMO

Type Float

Default value 0.003

Unit eV

GUI name HOMO energy convergence

Description Criterion for self-consistency procedure to terminate.

The self-consistent GW calculation terminates, when the difference between the HOMO QP energies between 2 consecutive iterations is below this number.

The LUMO energy converged faster than the HOMO energy so when the HOMO energy is converged according to this criterion, the LUMO energy will be converged as well.

In non-selfconsistent Calculation, this criterion is ignored.

DIIS

Type Integer

Default value 10

Description Requests to use DIIS. This is the Default. Number of expansion coefficients can be requested as well. Ignored in non-selfconsistent calculation

Enabled

Type Bool

Default value No

GUI name Calculate GW quasi-particle energies

Description Enable the calculation of the GW quasi-particle energies.

FixedGrids

Type Bool

Default value No

Description In a self-consistent GW calculation, do not recalculate Grids. Can be useful in case of convergence problems. Only relevant for qsGW and qsGW0. In case of evGW and evGW0, the grids are always kept fixed.

LinearMixing

Type Float List

Description Requests to use linear mixing instead of DIIS and sets the mixing parameter for linear mixing of Green's function in case of self-consistency.

It is ignored in non-selfconsistent calculation and overwritten by DIIS when DIIS is also present.

LinearizeQPequations

Type Bool

Default value No

Description Instead of solving the non-linear QP equations in a G0W0 (or evGW calculation) by bisection exacly, linearize them by first-order Taylor expansion.

This is not recommended since it does not save computational time when used together with analytical continuation (as implemented in AMS). It might however be useful for benchmarking or for validating results.

If the results os the linearization differ by a lot (for instance, more than 0.1 eV in frontier QP energies) from the non-linearized results, this might indicate that the GW calculation is not reliable.

OffDiagonalEFermi

Type Bool

Default value No

Description Analytically continue the off-diagonal elements of the KSF2 qsGW Hamiltonian at the Fermi-energy instead of omega=0. Typically leads to slightly lower QP energies, i.e. higher ionization potentials. The HOMO-LUMO gaps are typically not affected.

PrintAllSolutions

Type Bool

Default value No

Description Print out all solutions for all requested states. Detects multiple solutions of the QP equations.

QPHamiltonian

Type Multiple Choice

Default value KSF2

Options [KSF1, KSF2, SRG, LQSGW]

Description The quasi-particle Hamiltonian can be constructed in different ways.

KSF1 refers to the original construction by Kotani, Van Schilfgaarde anf Faleev (KSF) which is also implemented in TURBOMOLE.

KSF2 refers to an alternative construction by KSF.

KSF1 is not recommended since it is numerically less stable than KSF2. The results are typically very similar.

The QP energies at which the matrix elements are evaluated can be tweaked further, see the two subsequent keys: However, KSF2 is recommended since it typically leads to QP energies with the best agreement with experiment.

Ignored when not a quasi-particle self-consistent GW calculation is performed

ScissorShift

Type Bool

Default value No

Description Only calculate the HOMO and LUMO QP energies and shift the remaining QP energies by the same amount.

This is a rather crude approximaiton and not recommended.

It might again be useful for benchmarking purposes.

SelfConsistency

Type Multiple Choice

Default value G0W0

Options [G0W0, EVGW0, EVGW, QSGW0, QSGW]

Description Sets the level of self-consistency in a GW calculation.

G0W0 calculates a one-shot, perturbative correction to the KS eigenvalues.

In evGW and evGW0, the quasi-particle energies are updated until self-consistency is reached.

evGW0 requests that the Green's function is evaluated self-consistently but not the screened interaction.

In qsGW, the density is updated as well, however, the self-energy is mapped to a static effective potential and the Dyson equation is solved by diagonalization instead of inversion. The results of a qsGW are independent of the choice of the underlying exchange-correlation functional and are usually the most accurate ones.

The same is done in qsGW0, but the screened interaction is not updated.

SelfEnergy

Type Multiple Choice

Default value GW

Options [HF, GW, G3W2, SOSEX, GWGamma, G3W2dynamic]

Description Controls the form of the self-energy.

GW is the default and corresponds to the standard GW calculation.

G3W2 is a GW calculation plus a perturbative second-order statically screened exchange correction (second order expansion in the self-energy). Note, that there the self-energy is always static.

nIterations

Type Integer List

Default value [10]

GUI name Number of iterations

Description The maximum number of iterations within the (partially or fully) self-consistent GW calculation has to converge.

Ignored when Formalism is set to G0W0

nLowest

Type Integer

Default value 1

GUI name N Lowest

Description Number of lowest occupied QP levels to be evaluated, overwrites nStates'

nStates

    Type Integer

    Default value 5

    GUI name N states

    Description Number of Quasiparticle States to be printed to output.

        The default is 5 states which in this case means that min(5, Number of particle states) occupied and min(5, Number of hole states) hole states are printed. The whole list of states can be printed by setting this parameter to -1'

preconditionQSGW

    Type Bool

    Default value No

    Description If true, the QSGW equations are solved but prior to each diagonalization, i.e. a G0W0 calculation is performed to find the optimal QP energies at which to analytically continue the self-energy.

        This is in principle a more consistent construction than KSF1 or KSF2 since the diagonal elements are consistent with G0W0.

        In KSF1 and KSF2, the diagonal elements are evaluated at the QP energies from the previous iteration which is equivalent to a zeroth-order Taylor expansion of the diaognal elements around the previous QP energies.Enabling this option typically leads to slightly lower QP energies.

HubbardU

    Type Block

    Description Options for Hubbard-corrected DFT calculations.

    Atom

        Type Block

        Recurring True

        Description Specify Hubbard parameters (U,l) for a certain element

        Element

            Type String

            Description Name of the element, such as Cu or Zn

        LValue

            Type Multiple Choice

            Default value s

            Options [s, p, d, f]

            Description L value of the shell to apply the Hubbard model to

        UValue

            Type Float

>> **Default value** 0.0

>> **Unit** Hartree

>> **Description** Hubbard U value.

> **PrintOccupations**

>> **Type** Bool

>> **Default value** Yes

>> **Description** Whether or not to print the occupations during the SCF.

> **Region**

>> **Type** Block

>> **Recurring** True

>> **Description** Specify Hubbard parameters (U,l) for all atoms in a certain region

>> **LValue**

>>> **Type** Multiple Choice

>>> **Default value** s

>>> **Options** [s, p, d, f]

>>> **Description** L value of the shell to apply the Hubbard model to

>> **Name**

>>> **Type** String

>>> **Description** Name of the region

>> **UValue**

>>> **Type** Float

>>> **Default value** 0.0

>>> **Unit** Hartree

>>> **Description** Hubbard U value.

Integration

> **Type** Block

> **Description** Options for the Voronoi numerical integration scheme. Deprecated. Use BeckeGrid instead.

> **AccInt**

>> **Type** Float

>> **Default value** 3.5

>> **Description** General parameter controlling the accuracy of the Voronoi integration grid. A value of 3 would be basic quality and a value of 7 would be good quality.

IntegrationMethod

> **Type** Multiple Choice

> **Default value** Becke

> **Options** [Becke, Voronoi]

Description Choose the real-space numerical integration method. Note: the Voronoi integration scheme is deprecated.

KGrpX

    Type Integer

    Default value 5

    GUI name Number of K-points at once

    Description Absolute upper bound on the number of k-points processed together. This only affects the computational performance.

KSpace

    Type Block

    Description Options for the k-space integration (i.e. the grid used to sample the Brillouin zone)

    Quality

        Type Multiple Choice

        Default value Auto

        Options [Auto, GammaOnly, Basic, Normal, Good, VeryGood, Excellent]

        GUI name K-space

        Description Select the quality of the K-space grid used to sample the Brillouin Zone. If 'Auto', the quality defined in the 'NumericalQuality' will be used. If 'GammaOnly', only one point (the gamma point) will be used.

        The actual number of K points generated depends on this option and on the size of the unit cell. The larger the real space cell, the fewer K points will be generated.

        The CPU-time and accuracy strongly depend on this option.

    Regular

        Type Block

        Description Options for the regular k-space integration grid.

        NumberOfPoints

            Type Integer List

            Description Use a regular grid with the specified number of k-points along each reciprocal lattice vector.

            For 1D periodic systems you should specify only one number, for 2D systems two numbers, and for 3D systems three numbers.

    Symmetric

        Type Block

        Description Options for the symmetric k-space integration grid.

        KInteg

            Type Integer

            GUI name Accuracy

Description Specify the accuracy for the Symmetric method.

1: absolutely minimal (only the G-point is used) 2: linear tetrahedron method, coarsest spacing 3: quadratic tetrahedron method, coarsest spacing 4,6,… (even): linear tetrahedron method 5,7…. (odd): quadratic method

The tetrahedron method is usually by far inferior.

Type

Type Multiple Choice

Default value Regular

Options [Regular, Symmetric]

GUI name K-space grid type

Description The type of k-space integration grid used to sample the Brillouin zone (BZ) used.

'Regular': simple regular grid.

'Symmetric': symmetric grid for the irreducible wedge of the first BZ (useful when high-symmetry points in the BZ are needed to capture the correct physics of the system, graphene being a notable example).

LDOS

Type Block

Description Local Density-Of-States information. This can be used to generate STM images in the Tersoff-Hamann approximation (see https://doi.org/10.1103/PhysRevB.31.805)

DeltaNeg

Type Float

Default value 0.0001

Unit Hartree

Description Lower bound energy (Shift-DeltaNeg)

DeltaPos

Type Float

Default value 0.0001

Unit Hartree

Description Upper bound energy (Shift+DeltaPos)

Shift

Type Float

Default value 0.0

Unit Hartree

Description The energy bias with respect to the Fermi level.

MBPT

Type Block

Description Technical aspects of the MP2 algorithm.

Dependency

Type Bool

Default value Yes

Description If true, to improve numerical stability, almost linearly-dependent combination of basis functions are removed from the Green's function that are used in the MBPT equations. Disabeling this key is stringly discouraged. Its value can however be changed. The key to adjust this value is RiHartreeFock%DependencyThreshold

ExcludeCore

Type Bool

Description If active, excludes core states from the calculation of the optiomal imaginary time and frequency grids.

The core states are still included in all parts of the calculations.

In case a frozen care calculation is performed, this key is ignored.

For MP2 and double hybrid calculation, it defauls to false. For RPA and GW calculations, it defaults to true.

FitSetQuality

Type Multiple Choice

Default value Auto

Options [Auto, VeryBasic, Basic, Normal, Good, VeryGood]

Description Specifies the fit set to be used in the MBPT calculation.

'Normal' quality is generally sufficient for basis sets up to and including TZ2P.

For larger basis sets (or for benchmarking purposes) a 'VeryGood' fit set is recommended. Note that the FitSetQuality heavily influences the computational cost of the calculation.

If not specified or 'Auto', the RIHartreeFock%FitSetQuality is used.

Formalism

Type Multiple Choice

Default value Auto

Options [Auto, RI, LT, All]

Description Specifies the formalism for the calculation of the MP2 correlation energy.

'LT' means Laplace Transformed MP2 (also referred to as AO-PARI-MP2),

'RI' means that a conventional RI-MP2 is carried out.

If 'Auto', LT will be used in case of DOD double hybrids and SOS MP2, and RI will be used in all other cases.

'All' means that both RI and LT formalisms are used in the calculation.

For a RPA or GW calculation, the formalism is always LT, irrespective of the formalism specified with this key.

FrequencyGridType

Type Multiple Choice

Default value LeastSquare

Options [LeastSquare, GaussLegendre]

Description Use Gauss-legendre grid for imaginary frequency integration in RPA and GW calculations instead of the usually used Least-Square optimized ones. Has the advantage that it can be systematically converged and an arbitrary number of grid points can be used. Typically more grid points will be needed to get the same level of accuracy. However, the convergence of the results with the size of the grid can be more systematic. These grids can only be used when Formalism is set to RI.

IntegrationQuality

    Type Multiple Choice

    Options [VeryBasic, Basic, Normal, Good, VeryGood]

    Description Specifies the integration quality to be used in the MBPT calculation. If not specified, the RIHartreeFock%IntegrationQuality is used.

SigmaFunctionalParametrization

    Type Multiple Choice

    Default value S1re

    Options [W1, W2, S1, S2, S1re]

    Description Only relevant if a sigma-functional calculation is performed. Possible choices for the parametrization of the sigma-functional. Not all options are supported for all functionals.

ThresholdQuality

    Type Multiple Choice

    Options [VeryBasic, Basic, Normal, Good, VeryGood, Excellent]

    Description Controls the distances between atomic centers for which the product of two basis functions is not fitted any more. Especially for spatially extended, large systems, 'VERYBASIC' and 'BASIC' can lead to large computational savings, but the fit is also more approximate. If not specified, the RIHartreeFock%ThresholdQuality is used.

UseScaledZORA

    Type Bool

    Default value Yes

    Description If true, use the scaled ZORA orbital energies instead of the ZORA orbital energies in the MBPT equations.

frozencore

    Type Bool

    Default value No

    Description Freeze core states in correlation part of MBPT calculation

nCore

    Type Integer

    Default value 0

    GUI name Number of core levels

    Description Number of core states which will be excluded from the correlated calculation.

    Will be ignored if frozencore is false.

    In case nothing is specified, the number of core levels will be determined automatically.

Needs to be smaller than the number of occupied states.

nFrequency

> **Type** Integer
>
> **Default value** 12
>
> **GUI name** Number of frequency points
>
> **Description** Number of imaginary frequency points. This key is only relevant for RPA and GW and will be ignored if used in an AO-PARI-MP2 calculation. 12 Points is the default for a RPA calculation. It is technically possible to use a different number of imaginary frequency points than for imaginary time. The maximum number of points which can be requested for imaginary frequency integration is 42. Important note: The computation time and memory requirements roughyl scale linearly with the number of imaginary frequency points. However, memory can be an issue for RPA and GW when the number of imaginary frequency points is high. In case a job crashes, it is advised to increase the number of nodes since the necessary memory distributes over all nodes.

nFrequencyG3W2

> **Type** Integer
>
> **Default value** 32
>
> **GUI name** Number of frequency points for G3W2 integration
>
> **Description** Number of imaginary frequency points for G3W2 integration

nLambda

> **Type** Integer
>
> **Default value** 1
>
> **GUI name** Number of lambda points
>
> **Description** Size of coupling constant integration grid for SOSEX variants in RPA. Default is 4 points

nTime

> **Type** Integer
>
> **GUI name** Number of time points
>
> **Description** Number of imaginary time points (only relevant in case the Laplace Transformed (LT) formalism is used).
>
> In the many-body-perturbation theory module in ADF, the polarizability (or Kohn-Sham density response function) is evaluated in imaginary time to exploit sparsity in the AO basis. For MP2, this is often referred to as a Laplace transform. For MP2, 9 points are the default. This is a safe choice, guaranteeing accuracies higher than 1 Kj/mol for most systems (For many simple organic systems, 6 points are sufficient for good accuracy).
>
> Only for systems with a very small HOMO-LUMO gap or low-lying core states (heavy elements starting from the 4th row of the periodic table) more points might be necessary.
>
> In principle, the same considerations apply for RPA and GW as well, however, the accuracy requirements are somewhat higher and 12 point are the default for RPA. In a GW calculation, the number of points is adjusted according to the numerical quality. Using less than 9 points is strongly discouraged except for the simplest molecules.

In ADF2019, it can happen that the algorithm determining the imaginary time grid does not converge. In this case, the usual reason is that the number of points is too small and more points need to be specified. Starting from AMS2020, this does not happen any more. In case the imaginary time grid does not converge, the number of points is automatically adjusted until it does.

The computation time of AO-PARI-MP2, RPA, and GW scales linearly with the number of imaginary time points.

MolecularNMR

> **Type** Block
>
> **Description** Options for the calculations of the NMR shielding tensor for molecules, excluding periodic systems. Implements the Schreckenbach method like ADF.

> **Enabled**
>
> > **Type** Bool
> >
> > **Default value** No
> >
> > **Description** Compute NMR shielding.

MultiSecantConfig

> **Type** Block
>
> **Description** Parameters for the Multi-secant SCF convergence method.

> **CMax**
>
> > **Type** Float
> >
> > **Default value** 20.0
> >
> > **GUI name** Max coeff
> >
> > **Description** Maximum coefficient allowed in expansion

> **InitialSigmaN**
>
> > **Type** Float
> >
> > **Default value** 0.1
> >
> > **GUI name** Initial
> >
> > **Description** This is a lot like a mix factor: bigger means bolder

> **MaxSigmaN**
>
> > **Type** Float
> >
> > **Default value** 0.3
> >
> > **GUI name** Max
> >
> > **Description** Upper bound for the SigmaN parameter

> **MaxVectors**
>
> > **Type** Integer
> >
> > **Default value** 20
> >
> > **GUI name** Number of cycles to use
> >
> > **Description** Maximum number of previous cycles to be used

MinSigmaN

>> **Type** Float

>> **Default value** 0.01

>> **GUI name** Min

>> **Description** Lower bound for the SigmaN parameter

NEGF

> **Type** Block

> **Description** Options for the NEGF (non-equilibrium green function) transport calculation.

AlignChargeTol

>> **Type** Float

>> **Default value** 0.1

>> **Description** In an alignment run you want to get the number of electrons in the center right. This number specifies the criterion for that.

AlignmentFile

>> **Type** String

>> **Default value**

>> **Description** Band result file (.rkf) corresponding to the alignment calculation.

Alpha

>> **Type** Float

>> **Default value** 1e-05

>> **Description** A charge error needs to be translated in a potential shift. DeltaV = alpha * DeltaQ

ApplyShift1

>> **Type** Bool

>> **Default value** Yes

>> **Description** Apply the main shift, obtained from comparing matrix elements in the leads with those from the tight-binding run. Strongly recommended.

ApplyShift2

>> **Type** Bool

>> **Default value** Yes

>> **Description** Apply the smaller alignment shift. This requires an extra alignment run. Usually this shift is smaller.

AutoContour

>> **Type** Bool

>> **Default value** Yes

>> **Description** Use automatic contour integral.

BiasPotential

>> **Type** Float

Default value 0.0

Description Apply a bias potential (atomic units). Can be negative. One has to specify the ramp potential with the FuzzyPotential key. This is mostly conveniently done with the GUI.

BoundOccupationMethod

Type Integer

Default value 1

Description See text. Only relevant with NonEqDensityMethod equal 2 or 3.

CDIIS

Type Bool

Default value No

Description Make the normal DIIS procedure aware of the align charge error

CheckOverlapTol

Type Float

Default value 0.01

Description BAND checks how well the TB overlap matrix S(R=0) represents the overlap matrix in the lead region. Elements corresponding to the outer layer are neglected, because when using a frozen core they have bigger errors.

ContourQuality

Type Multiple Choice

Default value good

Options [basic, normal, good, verygood]

Description The density matrix is calculated numerically via a contour integral. Changing the quality influences the number of points. This influences a lot the performance.

DEContourInt

Type Float

Default value -1.0

Description The energy interval for the contour grid. Defaults depends on the contour quality

DERealAxisInt

Type Float

Default value -1.0

Description The energy interval for the real axis grid. Defaults depends on the contour quality.

DeltaPhi0

Type Float

Default value 0.0

Description Undocumented.

DeltaPhi1

Type Float

Default value 0.0

Description Undocumented.

DoAlignment

Type Bool

Default value No

Description Set this to True if you want to do an align run. Between the leads there should be lead material. The GUI can be of help here.

EMax

Type Float

Default value 5.0

Unit eV

Description The maximum energy for the transmission grid (with respect to the Fermi level of the lead)

EMin

Type Float

Default value -5.0

Unit eV

Description The minimum energy for the transmission grid (with respect to the Fermi level of the lead)

Eta

Type Float

Default value 1e-05

Description Small value used for the contour integral: stay at least this much above the real axis. This value is also used for the evaluation of the Transmission and dos.

IgnoreOuterLayer

Type Bool

Default value Yes

Description Whether or not to ignore the outer layer.

KT

Type Float

Default value 0.001

Description k-Boltzman times temperature.

LeadFile

Type String

Default value

Description File containing the tight binding representation of the lead.

NE

Type Integer

Default value 100

Description The number of energies for the transmission energy grid.

NonEqDensityMethod

Type Integer

Default value 1

Description See text.

SGFFile

Type String

Default value

Description The result from the SGF program. Contains the Fermi energy of the lead.

YContourInt

Type Float

Default value 0.3

Description The density is calculated via a contour integral. This value specifies how far above the real axis the (horizontal part of the) contour runs. The value is rounded in such a way that it goes exactly halfway between two Fermi poles. There is a trade off: making it bigger makes the integrand more smooth, but the number of enclosed poles increases. For low temperatures it makes sense to lower this value, and use a smaller deContourInt.

YRealaxisInt

Type Float

Default value 1e-05

Description The non-Equilibrium density is calculated near the real axis.

NeutralizingDensity

Type Multiple Choice

Default value None

Options [None, rho(atoms), rho(valence/atoms), rho(neutralizing/atoms), rho(homogeneous)]

Description For charged systems an artificial compensating density can be used to make it neutral again. This fictitious density only affects the Coulomb potential. For charged periodic systems neutralization is required, as otherwise the Coulomb potential diverges.

NeutralizingDensityDetails

Type Block

Description

DiffuseFactor

Type Float

Default value 1.0

Description The bigger this number, the more diffuse (extended) the neutralizing density becomes. Works only for rho(neutralizing/atoms)

HomogeneousDensity

> **Type** Block
>
> **Description** xxx

> **Origin**
>
> > **Type** Float List
> >
> > **Default value** [0.0, 0.0, 0.0]
> >
> > **Unit** Bohr
> >
> > **Description**

> **Range**
>
> > **Type** Float
> >
> > **Default value** 10.0
> >

> >
> > **Unit** Bohr
> >
> > **Description**

NewResponse

> **Type** Block
>
> **Description** The TD-CDFT calculation to obtain the dielectric function is computed when this block is present in the input. Several important settings can be defined here.

> **ActiveESpace**
>
> > **Type** Float
> >
> > **Default value** 5.0
> >
> > **Unit** eV
> >
> > **GUI name** Active energy space
> >
> > **Description** Modifies the energy threshold (DeltaE^{max}_{thresh} = omega_{high} + ActiveESpace) for which single orbital transitions (DeltaEpsilon_{ia} = Epsilon_{a}^{virtual} - Epsilon_{i}^{occupied}) are taken into account.

> **ActiveXYZ**
>
> > **Type** String
> >
> > **Default value** t
> >
> > **Description** Expects a string consisting of three letters of either 'T' (for true) or 'F' (for false) where the first is for the X-, the second for the Y- and the third for the Z-component of the response properties. If true, then the response properties for this component will be evaluated.

> **DensityCutOff**
>
> > **Type** Float

Default value 0.001

GUI name Volume cutoff

Description For 1D and 2D systems the unit cell volume is undefined. Here, the volume is calculated as the volume bordered by the isosurface for the value DensityCutoff of the total density.

EShift

> **Type** Float
>
> **Default value** 0.0
>
> **Unit** eV
>
> **GUI name** Shift
>
> **Description** Energy shift of the virtual crystal orbitals.

FreqHigh

> **Type** Float
>
> **Default value** 3.0
>
> **Unit** eV
>
> **Description** Upper limit of the frequency range for which response properties are calculated ($omega_{high}$).

FreqLow

> **Type** Float
>
> **Default value** 1.0
>
> **Unit** eV
>
> **Description** Lower limit of the frequency range for which response properties are calculated. ($omega_{low}$)

NFreq

> **Type** Integer
>
> **Default value** 5
>
> **Description** Number of frequencies for which a linear response TD-CDFT calculation is performed.

NewResponseKSpace

> **Type** Block
>
> **Description** Modify the details for the integration weights evaluation in reciprocal space for each single-particle transition. Only influencing the NewResponse code.

Eta

> **Type** Float
>
> **Default value** 1e-05
>
> **Description** Defines the small, finite imaginary number i*eta which is necessary in the context of integration weights for single-particle transitions in reciprocal space.

SubSimp

> **Type** Integer

Default value 3

Description determines into how many sub-integrals each integration around a k point is split. This is only true for so-called quadratic integration grids. The larger the number the better the convergence behavior for the sampling in reciprocal space. Note: the computing time for the weights is linear for 1D, quadratic for 2D and cubic for 3D!

NewResponseSCF

Type Block

Description Details for the linear-response self-consistent optimization cycle. Only influencing the NewResponse code.

Bootstrap

Type Integer

Default value 0

Description defines if the Berger2015 kernel (Bootstrap 1) is used or not (Bootstrap 0). If you chose the Berger2015 kernel, you have to set NewResponseSCF%XC to '0'. Since it shall be used in combination with the bare Coulomb response only. Note: The evaluation of response properties using the Berger2015 is recommend for 3D systems only!

COApproach

Type Bool

Default value Yes

Description The program automatically decides to calculate the integrals and induced densities via the Bloch expanded atomic orbitals (AO approach) or via the cyrstal orbitals (CO approach). The option COApproach overrules this decision.

COApproachBoost

Type Bool

Default value No

GUI name CO Approach Boost

Description Keeps the grid data of the Crystal Orbitals in memory.

Requires significantly more memory for a speedup of the calculation. One might have to use multiple computing nodes to not run into memory problems.

Criterion

Type Float

Default value 0.001

Description For the SCF convergence the RMS of the induced density change is tested. If this value is below the Criterion the SCF is finished.

Furthermore, one can find the calculated electric susceptibility for each SCF step in the output and can therefore decide if the default value is too loose or too strict.

DIIS

Type Block

Description Parameters influencing the DIIS self-consistency method

Enabled

Type Bool

Default value Yes

Description If not enabled simple mixing without DIIS acceleration will be used.

MaxSamples

Type Integer

Default value 10

Description Specifies the maximum number of samples considered during the direct inversion of iteration of subspace (DIIS) extrapolation of the atomic charges during the SCC iterations. A smaller number of samples potentially leads to a more aggressive convergence acceleration, while a larger number often guarantees a more stable iteration. Due to often occurring linear dependencies within the set of sample vectors, the maximum number of samples is reached only in very rare cases.

MaximumCoefficient

Type Float

Default value 10.0

Description When the diis expansion coefficients exceed this threshold, the solution is rejected. The vector space is too crowded. The oldest vector is discarded, and the expansion is re-evaluated.

MinSamples

Type Integer

Default value -1

Description When bigger than one, this affects the shrinking of the DIIS space on linear depence. It will not reduce to a smaller space than MinSamples unless there is extreme dependency.

MixingFactor

Type Float

Default value 0.2

Description The parameter used to mix the DIIS linear combination of previously sampled atomic charge vectors with an analogous linear combination of charge vectors resulting from population analysis combination. It can assume real values between 0 and 1.

LowFreqAlgo

Type Bool

Default value Yes

GUI name Low Frequency Algorithm

Description Numerically more stable results for frequencies lower than 1.0 eV. Note: for a graphene monolayer the conical intersection results in a very small band gap (zero band gap semi-conductor). This leads ta a failing low frequency algorithm. One can then chose to use the algoritm as originally proposed by Kootstra by setting the input value to *false*. But, this can result in unreliable results for frequencies lower than 1.0 eV!

NCycle

Type Integer

Default value 20

GUI name Cycles

Description Number of SCF cycles for each frequency to be evaluated.

XC

Type Integer

Default value 1

Description Influences if the bare induced Coulomb response (XC 0) is used for the effective, induced potential or the induced potential derived from the ALDA kernel as well (XC 1).

NMR

Type Block

Description Options for the calculations of the NMR shielding tensor.

Correction_r

Type Bool

Default value Yes

Description Undocumented.

Enabled

Type Bool

Default value No

Description Compute NMR shielding.

MS0

Type Float

Default value 0.01

Description Undocumented.

NMRAtom

Type Integer

Default value 0

Description The index of the atom atom (in input order) for which NMR should be computed.

Numeric

Type Bool

Default value No

Description Undocumented.

Original

Type Bool

Default value No

Description Undocumented.

Print_jp

Type Bool

Description Print paramagnetic current.

SuperCell

> **Type** Bool
>
> **Default value** Yes
>
> **Description** This is the switch between the two methods, either the super cell (true), or the single-dipole method (false)

Test

> **Type** Bool
>
> **Description** Key for printing all intrinsic tensors.

Test_E

> **Type** Bool
>
> **Description** Test of energy levels.

Test_S

> **Type** Bool
>
> **Description** Test of overlap matrix.

UseSharedMemory

> **Type** Bool
>
> **Default value** Yes
>
> **Description** Whether or not to use shared memory in the NMR calculation.

NOCVdRhoPlot

> **Type** Non-standard block
>
> **Description** Goes together with the Restart%NOCVdRhoPlot and Grid keys. See example.

NOCVOrbitalPlot

> **Type** Non-standard block
>
> **Description** Goes together with the Restart%NOCVOrbitalPlot and Grid keys. See example.

NuclearModel

> **Type** Multiple Choice
>
> **Default value** PointCharge
>
> **Options** [PointCharge, Gaussian, Uniform]
>
> **Description** Specify what model to use for the nucleus.
>
> For the Gaussian model the nuclear radius is calculated according to the work of Visscher and Dyall (L. Visscher, and K.G. Dyall, Dirac-Fock atomic electronic structure calculations using different nuclear charge distributions, Atomic Data and Nuclear Data Tables 67, 207 (1997))

NUElstat

> **Type** Integer
>
> **Default value** 50

Description Number of outward (parabolic) integration points (for elliptical integration of the electrostatic interaction)

NumericalQuality

Type Multiple Choice

Default value Normal

Options [Basic, Normal, Good, VeryGood, Excellent]

Description Set the quality of several important technical aspects of a BAND calculation (with the notable exception of the basis set). It sets the quality of: BeckeGrid (numerical integration), ZlmFit (density fitting), KSpace (reciprocal space integration), and SoftConfinement (basis set confinement). Note: the quality defined in the block of a specific technical aspects supersedes the value defined in NumericalQuality (e.g. if I specify 'NumericalQuality Basic' and 'BeckeGrid%Quality Good', the quality of the BeckeGrid will be 'Good')

NVElstat

Type Integer

Default value 80

Description Number of angular (elliptic) integration points (for elliptical integration of the electrostatic interaction)

Occupations

Type Non-standard block

Description Allows one to input specific occupations numbers. Applies only for calculations that use only one k-point (i.e. pseudo-molecule calculations). See example.

OldResponse

Type Block

Description Options for the old TD-CDFT implementation.

Berger2015

Type Bool

Default value No

Description Use the parameter-free polarization functional by A. Berger (Phys. Rev. Lett. 115, 137402). This is possible for 3D insulators and metals. Note: The evaluation of response properties using the Berger2015 is recommend for 3D systems only!

CNT

Type Bool

Description Use the CNT parametrization for the longitudinal and transverse kernels of the XC kernel of the homogeneous electron gas. Use this in conjunction with the NewVK option.

CNVI

Type Float

Default value 0.001

Description The first convergence criterion for the change in the fit coefficients for the fit functions, when fitting the density.

CNVJ

Type Float

Default value 0.001

Description the second convergence criterion for the change in the fit coefficients for the fit functions, when fitting the density.

Ebndtl

    Type Float

    Default value 0.001

    Unit Hartree

    Description the energy band tolerance, for determination which routines to use for calculating the numerical integration weights, when the energy band posses no or to less dispersion.

Enabled

    Type Bool

    Default value No

    Description If true, the response function will be calculated using the old TD-CDFT implementation

Endfr

    Type Float

    Default value 3.0

    Unit eV

    Description The upper bound frequency of the frequency range over which the dielectric function is calculated

Isz

    Type Integer

    Default value 0

    Description Integer indicating whether or not scalar zeroth order relativistic effects are included in the TDCDFT calculation. 0 = relativistic effects are not included, 1 = relativistic effects are included. The current implementation does NOT work with the option XC%SpinOrbitMagnetization equal NonCollinear

Iyxc

    Type Integer

    Default value 0

    Description integer for printing yxc-tensor (see http://aip.scitation.org/doi/10.1063/1.1385370). 0 = not printed, 1 = printed.

NewVK

    Type Bool

    Description Use the slightly modified version of the VK kernel (see https://aip.scitation.org/doi/10.1063/1.1385370). When using this option one uses effectively the static option, even for metals, so one should check carefully the convergence with the KSPACE parameter.

Nfreq

> **Type** Integer
>
> **Default value** 5
>
> **Description** the number of frequencies for which a linear response TD-CDFT calculation is performed.

QV

> **Type** Bool
>
> **Description** Use the QV parametrization for the longitudinal and transverse kernels of the XC kernel of the homogeneous electron gas. Use this in conjunction with the NewVK option. (see reference).

Shift

> **Type** Float
>
> **Default value** 0.0
>
> **Unit** eV
>
> **Description** energy shift for the virtual crystal orbitals.

Static

> **Type** Bool
>
> **Description** An alternative method that allows an analytic evaluation of the static response (normally the static response is approximated by a finite small frequency value). This option should only be used for non-relativistic calculations on insulators, and it has no effect on metals. Note: experience shows that KSPACE convergence can be slower.

Strtfr

> **Type** Float
>
> **Default value** 1.0
>
> **Unit** eV
>
> **Description** is the lower bound frequency of the frequency range over which the dielectric function is calculated.

OrbitalPlot

> **Type** Non-standard block
>
> **Description** Goes together with the Restart%OrbitalPlot and Grid keys. See Example.

Output

> **Type** Block
>
> **Description** Control the output.

Print

> **Type** Block
>
> **Recurring** True
>
> **Description**

Level

> > **Type** Multiple Choice

Options [None, Error, Warning, Minimal, Normal, Detail, TooMuchDetail]

Description

Section

Type Multiple Choice

Options [Prepare, SCF, Properties]

Description

OverlapPopulations

Type Non-standard block

Description Overlap population weighted DOS (OPWDOS), also known as the crystal orbital overlap population (COOP).

PEDA

Type Bool

Default value No

Description If present in combination with the fragment block, the decomposition of the interaction energy between fragments is invoked.

PEDANOCV

Type Block

Description Options for the decomposition of the orbital relaxation (pEDA).

EigvalThresh

Type Float

Default value 0.001

GUI name Use NOCVs with ev larger than

Description The threshold controls that for all NOCV deformation densities with NOCV eigenvalues larger than EigvalThresh the energy contribution will be calculated and the respective pEDA-NOCV results will be printed in the output

Enabled

Type Bool

Default value No

GUI name Perform PEDA-NOCV analysis

Description If true in combination with the fragment blocks and the pEDA key, the decomposition of the orbital relaxation term is performed.

PeriodicSolvation

Type Block

Description Additional options for simulations of periodic structures with solvation.

NStar

Type Integer

Default value 4

Description This option, expecting an integer number (>2), handles the accuracy for the construction of the COMSO surface. The larger the given number the more accurate the construction.

RemovePointsWithNegativeZ

Type Bool

Default value No

GUI name Only above slab

Description Whether the COSMO surface is constructed on both sides of a surface.

If one is only interested in the solvation effect on the upper side of a surface (in the Z direction), then this option should be set to 'True'

SymmetrizeSurfacePoints

Type Bool

Default value Yes

Description Whether or not the COSMO point should be symmetrized

PopThreshold

Type Float

Default value 0.01

Description Threshold for printing Mulliken population terms. Works with 'Print orbpop'

PotentialNoise

Type Float

Default value 0.0001

Description The initial potential for the SCF procedure is constructed from a sum-of-atoms density. Added to this is some small noise in the numerical values of the potential in the points of the integration grid. The purpose of the noise is to help the program break the initial symmetry, if that would lower the energy, by effectively inducing small differences between (initially) degenerate orbitals.

Print

Type String

Recurring True

Description One or more strings (separated by blanks) from a pre-defined set may be typed after the key. This induces printing of various kinds of information, usually only used for debugging and checking. The set of recognized strings frequently changes (mainly expands) in the course of software-developments. Useful arguments may be symmetry, and fit.

Programmer

Type Block

Description Miscellaneous technical options.

SharedMemorySandwichingThreshold

Type Integer

Default value 5000

Description When the nr. of basis functions exceeds this threshold shared memory will be used to calculate matrix elements.

Unless UseSharedMemoryForSandwiching is explicitly set in the input.

StoreDOSPerBas

Type Bool

Default value Yes

Description Whether or not to store the parial DOS per basis function. This allows you to view any partial DOS with amsspectra and amsbands. Requires the CalcPDOS option to be on.

StoreOrbitals

Type Bool

Default value Yes

Description Copy information on band.rkf needed for orbital plotting and restarts. This can be a lot of information. DOS and BandStructure require StoreOrbitals=true.

UpdateSTDVec

Type Bool

Default value Yes

Description Shift atoms so that center of mass is at zero. As a results the detected symmetry may be higher.

UseSharedMemoryForSandwiching

Type Bool

Default value Yes

GUI name Use shared memory

Description When calculating matrix elements the array will be shared. This saves memory at the cost of locking overhead.

If not specified this will depend on the threshold SharedMemorySandwichingThreshold

UseTurnoverRuleForXcMatrix

Type Bool

Default value No

Description Undocumented.

Usesharedmemory

Type Bool

Default value Yes

GUI name Use shared memory

Description When running more then one task, share memory between those tasks. This saves a lot of memory.

Only disable it in case of problems.

PropertiesAtNuclei

Type Non-standard block

Description A number of properties can be obtained near the nucleus. An average is taken over a tiny sphere around the nucleus. The following properties are available: vxc[rho(fit)], rho(fit), rho(scf), v(coulomb/scf), rho(deformation/fit), rho(deformation/scf).

RadialDefaults

> **Type** Block
>
> **Description** Options for the logarithmic radial grid of the basis functions used in the subprogram Dirac

> **NR**
>
> > **Type** Integer
> >
> > **Default value** 3000
> >
> > **Description** Number of radial points. With very high values (like 30000) the Dirac subprogram may not converge.

> **NRPerType**
>
> > **Type** Integer List
> >
> > **Description** If present overrides NR. The list needs to be as long as there are atom types

> **RMax**
>
> > **Type** Float
> >
> > **Default value** 100.0
> >
> > **Unit** Bohr
> >
> > **Description** Upper bound of the logarithmic radial grid

> **RMin**
>
> > **Type** Float
> >
> > **Default value** 1e-06
> >
> > **Unit** Bohr
> >
> > **Description** Lower bound of the logarithmic radial grid

> **RMinPerType**
>
> > **Type** Float List
> >
> > **Unit** Bohr
> >
> > **Description** If specified overrides RMin. The list needs to be as long as there are atom types (different elements)

Relativity

> **Type** Block
>
> **Description** Options for relativistic effects.

> **Level**
>
> > **Type** Multiple Choice
> >
> > **Default value** Scalar
> >
> > **Options** [None, Scalar, Spin-Orbit]
> >
> > **GUI name** Relativity (ZORA)

Description None: No relativistic effects.

Scalar: Scalar relativistic ZORA. This option comes at very little cost.

SpinOrbit: Spin-orbit coupled ZORA. This is the best level of theory, but it is (4-8 times) more expensive than a normal calculation. Spin-orbit effects are generally quite small, unless there are very heavy atoms in your system, especially with p valence electrons (like Pb).

See also the SpinOrbitMagnetization key.

ResponseInducedDensityPlot

Type Non-standard block

Description Goes together with Restart%ResponseInducedDensityPlot and Grid.

Restart

Type Block

Description Tells the program that it should restart with the restart file, and what to restart.

BandStructure

Type Bool

Default value No

Description Calculate the band structure from a previos calculation. Does not work with model potentials and Hubbard.

CheckAtomicPositions

Type Bool

Default value Yes

Description If set to True: For restarting the SCF the atomic positions will be checked, and may not deviate too much.

DOS

Type Bool

Default value No

Description Calculate the DOS from a previous calculation. Does not work with model potentials and Hubbard.

DensityPlot

Type Bool

Default value No

Description Goes together with the DensityPlot block and Grid blocks

File

Type String

Default value

Description Name of the restart file.

LoadEigenSystem

Type Bool

Default value No

GUI name Load: eigen system

Description At each step of the SCF load the section eigensystem from the restart file, forcing constant eigenvalues and vectors.

NOCVOrbitalPlot

Type Bool

Default value No

Description Goes together with the NOCVOrbitalPlot and Grid blocks.

NOCVdRhoPlot

Type Bool

Default value No

Description Goes together with the NOCVdRhoPlot and Grid blocks.

OrbitalPlot

Type Bool

Default value No

Description Goes together with the OrbitalPlot and Grid

ResponseInducedDensityPlot

Type Bool

Default value No

Description Goes together with the ResponseInducedDensityPlot and Grid blocks.

SCF

Type Bool

Default value No

GUI name Restart: SCF

Description Continue the SCF procedure using the orbital coefficients and occupations from the restart file.

UseDensityMatrix

Type Bool

Default value No

Description If set to True: For restarting the SCF the density matrix will be used. Requires you to set 'Save DensityMatrix' in the previous run.

VTKFile

Type String

Default value

Description If specified a vtk file with be created with this name. If the extension is '.txt', a text file is created. Setting it to 'CUBE' one or more (one for each component) files in the cube format are generated with an automatic naming scheme.

VoronoiGrid

Type Bool

Default value No

Description Copy the section Num In Params to the current file.

RIHartreeFock

>   **Type** Block
>
>   **Description**

DependencyCoreRange

>   **Type** Float
>
>   **Description** Basis functions may be given a core character based on the range. For now only active in Band and only if present in the input

DependencyThreshold

>   **Type** Float
>
>   **Default value** 0.001
>
>   **Description** To improve numerical stability, almost linearly-dependent combination of basis functions are removed from the Hartree-Fock exchange matrix.
>
>   If you obtain unphysically large bond energy in an Hybrid calculation, or an unphysically low correlation energy in an RPA, MP2, or double hybrid calculation, you might try setting the DependencyThreshold to a larger value (e.g. 3.0E-3)
>
>   Note, that in GW calculations and GW-BSE calculations the default for this key is 5.0e-3.

FitGenerationDetails

>   **Type** Block
>
>   **Description** Technical details about how the RI Hartree-Fock fit functions are generated.

BoostL

>   **Type** Bool
>
>   **Default value** No
>
>   **Description** Add extra max(l)+1 diffuse function
>
>   When l denotes the highest angular momentum present in the primary basis,
>
>   FromBasisProducts will generate auxiliary fit functions with up to 2l angular momentum.
>
>   When this key is set to true, the maximum angular momentum in the auxiliary fit set becomes 2l+2.
>
>   Typically, this option is not needed and when precision issues arise, it is rather advised to adjust the OneCenterDependencyThreshold key to a smaller value.

LapackWorkAround

>   **Type** Bool
>
>   **Default value** No
>
>   **Description** GetFitFunctionsForAtomType diagonalization done with Lapack instead of Scalapack

Method

>   **Type** Multiple Choice

Default value Auto

Options [Auto, FromBasisProducts]

Description The way in which fit functions are generated. The main distinction is whether it depends on the basis functions used.

When FromBasisProducts is used, the auxiliary basis is generated directly from the products of primary basis functions.

This has the advantage that the auxiliary fit adapts automatcally to the basis set size.

Especially for basis sets of QZ quality or larger, this is often necessary to otbain highly precise correlation energies using RPA or double hybrids

FromBasisProducts option is also useful for GW or BSE calculations with basis sets of QZ quality or larger.

OneCenterDependencyThreshold

Type Float

Default value 1e-08

Description This key is only active when FromBasisProducts is chosen as method to generate the auxiliary basis.

This threshold controls the size, and at the samw time, the precision of the auxiliary basis set. A smaller number leads to a larger auxiliary fit set.

The default value of 1e-8 is typically sufficient to converge correlation energies and QP energies to a very high precision.

It corresponds to an auxiliary basis which is typically 8-9 times larger than the primary basis.

UseBandRadialGrid

Type Bool

Default value Yes

Description Only applies to band. The band logarithmic grid ranges (by default) from 1e-6 to 100 with 3000 points. Otherwise 300 points will be used.

For 0-periodicity (molecules) it is advaisable to set this key to false since lots of memory is needed to evaluate all necessary integrals.

FitSetQuality

Type Multiple Choice

Default value Auto

Options [Auto, VeryBasic, Basic, Normal, Good, VeryGood, Excellent, FromBasisProducts]

Description The quality of auxiliary fit set employed in the RI scheme.

If 'Auto', the value of the RIHartreeFock Quality option will be used.

Normal quality is generally sufficient for basis sets up to and including TZ2P.

For larger basis sets (or for benchmarking purposes) a VeryGood fit set is recommended.

Note that the FitSetQuality heavily influences the computational cost of the calculation.

IntegrationQuality

Type Multiple Choice

Options [VeryBasic, Basic, Normal, Good, VeryGood, Excellent]

Description Quality of the numerical integration for evaluating the integrals between basis functions and fit functions. If IntegrationQuality is not defined in input, the value defined in RI-HartreeFock%Quality will be used.

Quality

> **Type** Multiple Choice
>
> **Default value** Auto
>
> **Options** [Auto, VeryBasic, Basic, Normal, Good, VeryGood, Excellent]
>
> **Description** Numerical accuracy of the RI procedure. If 'Auto', the quality specified in the 'NumericalQuality' will be used.

QualityPerRegion

> **Type** Block
>
> **Recurring** True
>
> **Description** Sets the fit-set quality for all atoms in a region. If specified, this overwrites the globally set quality.

> **Quality**
>
> > **Type** Multiple Choice
> >
> > **Options** [VeryBasic, Basic, Normal, Good, VeryGood, Excellent]
> >
> > **Description** This region's quality of the auxiliary fit set employed in the RI scheme.

> **Region**
>
> > **Type** String
> >
> > **Description** The identifier of the region for which to set the quality.

ResponseQuality

> **Type** Multiple Choice
>
> **Options** [VeryBasic, Basic, Normal, Good, VeryGood, Excellent]
>
> **Description** Numerical accuracy of the RI procedure for the Response module.

ThresholdQuality

> **Type** Multiple Choice
>
> **Options** [VeryBasic, Basic, Normal, Good, VeryGood, Excellent]
>
> **Description** Linear scaling thresholds (also used for determining at what range the multiple approximation is used). To disable all linear scaling thresholds set this to Excellent.

UseMe

> **Type** Bool
>
> **Default value** Yes
>
> **Description** Set to False if you want to use the old RI scheme (ADF only)

Save

> **Type** String
>
> **Recurring** True

Description Save scratch files or extra data that would be otherwise deleted at the end of the calculation.
e.g. 'TAPE10' (containing the integration grid) or 'DensityMatrix'

SCF

    Type Block

    Description Controls technical SCF parameters.

    Eigenstates

        Type Bool

        Description The program knows two alternative ways to evaluate the charge density iteratively in the SCF procedure: from the P-matrix, and directly from the squared occupied eigenstates. By default the program actually uses both at least one time and tries to take the most efficient. If present, Eigenstates turns off this comparison and lets the program stick to one method (from the eigenstates).

    Iterations

        Type Integer

        Default value 300

        GUI name Maximum number of cycles

        Description The maximum number of SCF iterations to be performed.

    Method

        Type Multiple Choice

        Default value MultiStepper

        Options [DIIS, MultiSecant, MultiStepper]

        Description Choose the general scheme used to converge the density in the SCF. In case of scf problems one can try the MultiSecant alternative at no extra cost per SCF cycle. For more details see the DIIS and MultiSecantConfig block.

    Mixing

        Type Float

        Default value 0.075

       Description Initial 'damping' parameter in the SCF procedure, for the iterative update of the potential: new potential = old potential + mix (computed potential-old potential). Note: the program automatically adapts Mixing during the SCF iterations, in an attempt to find the optimal mixing value.

    MultiStepperPresetPath

        Type String

        Default value DFTB/default2023.inc

        Description Name of file containing a SCFMultiStepper key block. This will be used if no Explicit SCFMultiStepper block is in the input, and Method=MultiStepper. If the path is not absolute, it is relative to $AMSHOME/data/presets/multi_stepper'

    PMatrix

        Type Bool

        Description If present, evaluate the charge density from the P-matrix. See also the key Eigenstates.

PrintAllOccupiedBands

> **Type** Bool
>
> **Default value** Yes
>
> **Description** When printing the ranges of the bands, include all occupied ones.

PrintAllVirtualBands

> **Type** Bool
>
> **Default value** No
>
> **Description** When printing the ranges of the bands, include all virtual ones.

PrintAlwaysBandRanges

> **Type** Bool
>
> **Default value** No
>
> **Description** Normally the ranges of the bands are only printed at the last SCF cycle

Rate

> **Type** Float
>
> **Default value** 0.99
>
> **Description** Minimum rate of convergence for the SCF procedure. If progress is too slow the program will take measures (such as smearing out occupations around the Fermi level, see key Degenerate of block Convergence) or, if everything seems to fail, it will stop

SCFMultiStepper

> **Type** Block
>
> **Description** To solve the self-consistent problem multiple steppers can be tried during stints using the ones that give the best progress.

> **AlwaysChangeStepper**
>
> > **Type** Bool
> >
> > **Default value** No
> >
> > **Description** When the progress is fine there is no reason to change the stepper. In practice this is always set to true, because also the Stepper%ExpectedSlope can be used to achieve similar behavior.

> **ErrorGrowthAbortFactor**
>
> > **Type** Float
> >
> > **Default value** 1000.0
> >
> > **Description** Abort stint when the error grows too much, compared to the error at the start of the stint.

> **FractionalStepFactor**
>
> > **Type** Float
> >
> > **Default value** -1.0
> >
> > **Description** Multiply the step by this factor. If smaller than zero this is not used.

> **MinStintCyclesForAbort**

Type Integer

Default value 0

Description Look at ErrorGrowthAbortFactor only when a number of steps has been completed since the start of the stint. A value of 0 means always.

Stepper

Type Block

Recurring True

Description ??

AbortSlope

Type Float

Default value 100.0

Description If the slope (at the end of a stint) is larger than this: abort the stepper

DIISStepper

Type Block

Description DIIS stepper

EDIISAlpha

Type Float

Default value 0.01

Description The extra energy vector is weighed by this factor. .

MaxCoefficient

Type Float

Default value 20.0

Description The largest allowed value of the expansion coefficients. If exceed the number of vectors is reduces until the criterion is met.

MaxVectors

Type Integer

Default value 10

Description Maximum number of previous densities to be used (size of the history).

MinVectors

Type Integer

Default value -1

Description Try to prevent to make nVectors shrink below this value, by allowing for significantly larger coeffcients.

Mix

Type Float

Default value 0.2

Description Also known as greed. It determines the amount of output density to be used. May be changed by the MixAdapter.

ErrorGrowthAbortFactor

    Type Float

    Default value -1.0

    Description Abort stint when the error grows too much, compared to the error at the start of the stint. Overides global ErrorGrowthAbortFactor when set to a value > 0

ExpectedSlope

    Type Float

    Default value -100.0

    Description If the slope of the total SCF is better than this keep on going.

FractionalStepFactor

    Type Float

    Default value -1.0

    Description Multiply the step by this factor. If smaller than zero this is not used.

MaxInitialError

    Type Float

    Description Only use the stepper when error is smaller than this.

MaxIterationNumber

    Type Integer

    Default value -1

    Description Stepper will only be active for iterations smaller than this number. (Negative value means: Ignore this option)

MaxStintNumber

    Type Integer

    Default value -1

    Description Stepper will only be active for stints smaller than this number. (Negative value means: Ignore this option)

MinInitialError

    Type Float

    Description Only use the stepper when error is larger than this.

MinIterationNumber

    Type Integer

    Default value -1

    Description Stepper will only be active for iterations larger than this number.

MinStintCyclesForAbort

    Type Integer

Default value 0

Description Look at ErrorGrowthAbortFactor only when a number of steps has been completed since the start of the stint. A value of 0 means always. Overides global value.

MinStintNumber

Type Integer

Default value -1

Description Stepper will only be active for stints larger than this number.

MixAdapter

Type Block

Description Generic mix adapter

ErrorGrowthPanicFactor

Type Float

Default value 10.0

Description When the error increases more than this factor, this mix is reduced a lot.

GrowthFactor

Type Float

Default value 1.1

Description When the mix is considered too low it is multiplied by this factor. Otherwise it is divided by it.

MaxMix

Type Float

Default value 0.3

Description Do not grow the mix above this value.

MinMix

Type Float

Default value 0.1

Description Do not shrink the mix below this value.

NTrialMixFactors

Type Integer

Default value 3

Description Only used with Type=Trial. Must be an odd number.

TrialMode

Type Multiple Choice

Default value CurrentMixCentered

Options [CurrentMixCentered, FullRange]

Description How are the NTrialMixFactors chosen?

Type

> > > **Type** Multiple Choice
> > >
> > > **Default value** Error
> > >

> > > >
> > > > **Description** There are several version of the Multi secant method.

> > **StintLength**
> >
> > > **Type** Integer
> > >
> > > **Description** Override global StintLength.

> **StintLength**
>
> > **Type** Integer

Default value 10

Description A stepper is active during a number of SCF cycles, called a stint.

UsePreviousStintForErrorGrowthAbort

Type Bool

Default value No

Description The error is normally checked against the first error of the stint. With this option that will be the one from the previous stint, if performed with the same stepper.

VSplit

Type Float

Default value 0.05

Description To disturb degeneracy of alpha and beta spin MOs the value of this key is added to the beta spin potential at the startup.

Screening

Type Block

Description For the periodic solvation potential and for the old (not default anymore) fitting method, BAND performs lattice summations which are in practice truncated. The precision of the lattice summations is controlled by the options in this block.

CutOff

Type Float

Description Criterion for negligibility of tails in the construction of Bloch sums. Default depends on Accuracy.

DMadel

Type Float

Description One of the parameters that define the screening of Coulomb-potentials in lattice sums. Depends by default on Accuracy, rmadel, and rcelx. One should consult the literature for more information

NoDirectionalScreening

Type Bool

Description Real space lattice sums of slowly (or non-) convergent terms, such as the Coulomb potential, are computed by a screening technique. In previous releases, the screening was applied to all (long-range) Coulomb expressions. Screening is only applied in the periodicity directions. This key restores the original situation: screening in all directions

RCelx

Type Float

Description Max. distance of lattice site from which tails of atomic functions will be taken into account for the Bloch sums. Default depends on Accuracy.

RMadel

Type Float

Description One of the parameters that define screening of the Coulomb potentials in lattice summations. Depends by default on Accuracy, dmadel, rcelx. One should consult the literature for more information.

SelectedAtoms

Type Integer List

Description With this key you can select atoms. This has an effect on a few of options, like NMR and EFG.

Skip

Type String

Recurring True

Description Skip the specified part of the Band calculation (expert/debug option).

SoftConfinement

Type Block

Description In order to make the basis functions more compact, the radial part of the basis functions is multiplied by a Fermi-Dirac (FD) function (this 'confinement' is done for efficiency and numerical stability reasons). A FD function goes from one to zero, controlled by two parameters. It has a value 0.5 at Radius, and the decay width is Delta.

Delta

Type Float

Unit Bohr

Description Explicitely specify the delta parameter of the Fermi-Dirac function (if not specified, it will be 0.1*Radius).

Quality

Type Multiple Choice

Default value Auto

Options [Auto, Basic, Normal, Good, VeryGood, Excellent]

GUI name Confinement

Description In order to make the basis functions more compact, the radial part of the basis functions is multiplied by a Fermi-Dirac (FD) function (this 'confinement' is done for efficiency and numerical stability reasons). A FD function goes from one to zero, controlled by two parameters. It has a value 0.5 at Radius, and the decay width is Delta.

This key sets the two parameters 'Radius' and 'Delta'.

Basic: Radius=7.0, Delta=0.7; Normal: Radius=10.0, Delta=1.0; Good: Radius=20.0, Delta=2.0; VeryGood and Excellent: no confinement at all.

If 'Auto', the quality defined in the 'NumericalQuality' will be used.

Radius

Type Float

Unit Bohr

Description Explicitely specify the radius parameter of the Fermi-Dirac function.

Solvation

Type Block

Description Options for the COSMO (Conductor like Screening Model) solvation model.

CVec

> **Type** Multiple Choice
>
> **Default value** EXACT
>
> **Options** [EXACT, FITPOT]
>
> **GUI name** Calculate Coulomb interaction
>
> **Description** Choose how to calculate the Coulomb interaction matrix between the molecule and the point charges on the surface:
>
> > - EXACT: use exact density, and integrate against the potential of the point charges. This may have inaccuracies when integration points are close to the point charges.
> >
> > - FITPOT: evaluate the molecular potential at the positions of the point charges, and multiply with these charges.

Charge

> **Type** Block
>
> **Description** Select the algorithm to determine the charges.

> **Conv**
>
> > **Type** Float
> >
> > **Default value** 1e-08
> >
> > **Description** Charge convergence threshold in iterative COSMO solution.

> **Corr**
>
> > **Type** Bool
> >
> > **Default value** Yes
> >
> > **GUI name** Correct for outlying charge
> >
> > **Description** Correct for outlying charge.

> **Iter**
>
> > **Type** Integer
> >
> > **Default value** 1000
> >
> > **Description** Maximum number of iterations to solve COSMO equations.

> **Method**
>
> > **Type** Multiple Choice
> >
> > **Default value** CONJ
> >
> > **Options** [CONJ, INVER]
> >
> > **GUI name** Charge determination method
> >
> > **Description** INVER: matrix inversion, CONJ: biconjugate gradient method.
> >
> > > The CONJ method is guaranteed to converge with small memory requirements and is normally the preferred method.

Enabled

>**Type** Bool
>
>**Default value** No
>
>**GUI name** Include COSMO solvation
>
>**Description** Use the Conductor like Screening Model (COSMO) to include solvent effects.

Radii

>**Type** Non-standard block
>
>**Description** The values are the radii of the atomic spheres. If not specified the default values are those by Allinge. Format: 'AtomType value'. e.g.: 'H 0.7'

SCF

>**Type** Multiple Choice
>
>**Default value** VAR
>
>**Options** [VAR, PERT, NONE]
>
>**GUI name** Handle charges
>
>**Description** Determine the point charges either Variational (VAR) or after the SCF as a Perturbation (PERT).

Solvent

>**Type** Block
>
>**Description** Solvent details

>**Del**
>
>>**Type** Float
>>
>>**Description** Del is the value of Klamt's delta_sol parameter, only relevant in case of Klamt surface.

>**Emp**
>
>>**Type** Float
>>
>>**Description** Emp is the empirical scaling factor x for the energy scaling.

>**Eps**
>
>>**Type** Float
>>
>>**Description** User-defined dielectric constant of the solvent (overrides the Eps value of the solvent defined in 'Name')

>**Name**
>
>>**Type** Multiple Choice
>>
>>**Default value** Water
>>
>>**Options** [AceticAcid, Acetone, Acetonitrile, Ammonia, Aniline, Benzene, BenzylAlcohol, Bromoform, Butanol, isoButanol, tertButanol, CarbonDisulfide, CarbonTetrachloride, Chloroform, Cyclohexane, Cyclohexanone, Dichlorobenzene, DiethylEther, Dioxane, DMFA, DMSO, Ethanol, EthylAcetate, Dichloroethane, EthyleneGlycol, Formamide, FormicAcid, Glycerol, HexamethylPhosphoramide, Hexane, Hydrazine, Methanol, MethylEthylKetone, Dichloromethane, Methylformamide, Methypyrrolidinone, Nitrobenzene, Nitrogen,

Nitromethane, PhosphorylChloride, IsoPropanol, Pyridine, Sulfolane, Tetrahydrofuran, Toluene, Triethylamine, TrifluoroaceticAcid, Water]

GUI name Solvent

Description Name of a pre-defined solvent. A solvent is characterized by the dielectric constant (Eps) and the solvent radius (Rad).

Rad

Type Float

Unit Angstrom

Description User-defined radius of the solvent molecule (overrides the Rad value of the solvent defined in 'Name').

Surf

Type Multiple Choice

Default value Delley

Options [Delley, Wsurf, Asurf, Esurf, Klamt]

GUI name Surface type

Description Within the COSMO model the molecule is contained in a molecule shaped cavity.

Select one of the following surfaces to define the cavity:

- Wsurf: Van der Waals surface - Asurf: solvent accessible surface - Esurf: solvent excluding surface - Klamt: Klamt surface - Delley: Delley surface.

SolvationSM12

Type Block

Description Options for Solvation Model 12 (SM12).

ARO

Type Float

Default value 0.0

Description Square of the fraction of non-hydrogen atoms in the solvent that are aromatic carbon atoms (carbon aromaticity)

Acid

Type Float

Default value 0.82

Description Abraham hydrogen bond acidity parameter

Base

Type Float

Default value 0.35

Description Abraham hydrogen bond bacicity parameter

BornC

Type Float

Default value 3.7

Description Coulomb constant for General Born Approximation

BornRadiusConfig

    Type Block

    Description

    MaxCellDistance

        Type Float

        Default value 30.0

        Unit Bohr

        Description Max distance from the centra cell used when computing the Born radii for periodic systems

    PointsPerBohr

        Type Integer

        Default value 10

        Description

    UseLegendreGrid

        Type Bool

        Default value Yes

        Description

Chgal

    Type Float

    Default value 2.474

    Description Exponential of Pauli's bond order

Cust

    Type String

    Description Custom solvent input

Debug

    Type String

    Description Prints a lot of information about every pass on CDS and ENP code, keywords: ENP, CDS

EPS

    Type Float

    Default value 78.36

    Description The dielectric constant

Enabled

    Type Bool

    Default value No

    GUI name Include SM12 solvation

Description Whether to use the Solvation Model 12 (SM12) in the calculation.

HALO

    Type Float

    Default value 0.0

    Description Square of the fraction of non-hydrogen atoms in the solvent molecule that are F, Cl, or Br (electronegative halogenicity)

Kappa

    Type Float

    Default value 0.0

    Description Factor for Debye screening

PostSCF

    Type Bool

    Default value No

    Description Whether to apply the solvation potential during the SCF or only calculate the solvation energy after the SCF.

PrintSM12

    Type Bool

    Default value No

    Description Prints out an in-depth breakdown of solvation energies

RadSolv

    Type Float

    Default value 0.4

    Description The radius distance between the solute and solvent

Ref

    Type Float

    Default value 1.3328

    Description Refractive index of solvent

Solv

    Type Multiple Choice

    Default value WATER

    Options [ACETICACID, ACETONITRILE, ACETOPHENONE, ANILINE, ANISOLE, BENZENE, BENZONITRILE, BENZYLALCOHOL, BROMOBENZENE, BROMOETHANE, BROMOFORM, BROMOOCTANE, N-BUTANOL, SEC-BUTANOL, BUTANONE, BUTYLACETATE, N-BUTYLBENZENE, SEC-BUTYLBENZENE, T-BUTYLBENZENE, CARBONDISULFIDE, CARBONTETRACHLORIDE, CHLOROBENZENE, CHLOROFORM, CHLOROHEXANE, M-CRESOL, CYCLOHEXANE, CYCLOHEXANONE, DECALIN, DECANE, DECANOL, 1-2-DIBROMOETHANE, DIBUTYLETHER, O-DICHLOROBENZENE, 1-2-DICHLOROETHANE, DIETHYLETHER, DIISOPROPYLETHER, N-N-DIMETHYLACETAMIDE, N-N-DIMETHYLFORMAMIDE, 2-6-DIMETHYLPYRIDINE, DIMETHYLSULFOXIDE, DODECANE, ETHANOL,

> ETHOXYBENZENE, ETHYLACETATE, ETHYLBENZENE, FLUOROBENZENE, 1-FLUORO-N-OCTANE, HEPTANE, HEPTANOL, HEXADECANE, HEXADE-CYLIODIDE, HEXANE, HEXANOL, IODOBENZENE, ISOBUTANOL, ISOOC-TANE, ISOPROPANOL, ISOPROPYLBENZENE, P-ISOPROPYLTOLUENE, MESITYLENE, METHANOL, METHOXYETHANOL, METHYLENECHLORIDE, N-METHYLFORMAMIDE, 2-METHYLPYRIDINE, 4-METHYL-2-PENTANONE, NITROBENZENE, NITROETHANE, NITROMETHANE, O-NITROTOLUENE, NONANE, NONANOL, OCTANE, OCTANOL, PENTADECANE, PENTANE, PENTANOL, PERFLUOROBENZENE, PHENYLETHER, PROPANOL, PYRI-DINE, TETRACHLOROETHENE, TETRAHYDROFURAN, TETRAHYDROTH-IOPHENEDIOXIDE, TETRALIN, TOLUENE, TRIBUTYLPHOSPHATE, TRI-ETHYLAMINE, 1-2-4-TRIMETHYLBENZENE, UNDECANE, WATER, XYLENE, 1-2-DIBROMOETHANE_WATER, 1-2-DICHLOROETHANE_WATER, BEN-ZENE_WATER, CARBONTETRACHLORIDE_WATER, CHLOROBENZENE_WATER, CHLOROFORM_WATER, CYCLOHEXANE_WATER, DIBUTYLETHER_WATER, DIETHYLETHER_WATER, ETHYLACETATE_WATER, HEPTANE_WATER, HEX-ANE_WATER, NITROBENZENE_WATER, OCTANOL_WATER]

GUI name Solvent

Description List of predefined solvents

Tens

Type Float

Default value 103.62

Description Macroscopic surface tension of the solvent at the air/solvent interface at 298K (cal*mol^-1*Ang^-2)

TopologicalExtrapolation

Type Block

Description Method to extrapolate the long range Coulomb potential, needed for periodic calculations

FirstCell

Type Integer

Default value 5

Description First cell for the topological extrapolation of the long range part of the Coulomb Potential.

LastCell

Type Integer

Default value 10

Description Last cell for the topological extrapolation of the long range part of the Coulomb Potential.

Order

Type Integer

Default value 3

Description Order of the topological extrapolation of the long range part of the Coulomb Potential.

StopAfter

> **Type** String
>
> **Default value** BAND
>
> **Description** Specifies that the program is stopped after execution of a specified program-part (subroutine).

StoreHamAsMol

> **Type** Bool
>
> **Default value** No
>
> **Description** Undocumented, used for (at least) NEGF.

StoreHamiltonian

> **Type** Bool
>
> **Description** Undocumented.

StoreHamiltonian2

> **Type** Bool
>
> **Default value** No
>
> **Description** determine the tight-binding representation of the overlap an fock matrix. Used for (at least) NEGF.

StrainDerivatives

> **Type** Block
>
> **Description** Undocumented.

> **Analytical**
>
> > **Type** Bool
> >
> > **Description** Whether or not to use analytical strain derivatives. By default this is determined automatically, and used if possible.

> **AnalyticalElectrostatic**
>
> > **Type** Bool
> >
> > **Default value** No
> >
> > **Description** Undocumented.

> **Analyticalkinetic**
>
> > **Type** Bool

> > **Description** Undocumented.

> **Analyticalpulay**
>
> > **Type** Bool
> >
> > **Default value** No
> >
> > **Description** Undocumented.

> **Analyticalxc**

Type Bool

Default value No

Description Undocumented.

Celltopoorder

Type Integer

Default value 20

Description Undocumented.

Coreorthoption

Type Integer

Default value 2

Description Undocumented.

Fitrho0numintextrarad

Type Integer

Default value 0

Description Undocumented.

Fitrho0prune

Type Bool

Default value Yes

Description Undocumented.

Kinviadagger

Type Bool

Default value No

Description Undocumented.

Lmaxmultipoleexpansion

Type Integer

Default value 4

Description Undocumented.

Naiveelstat

Type Bool

Default value No

Description Undocumented.

Numericaldefdef

Type Bool

Default value Yes

Description Undocumented.

Numericaldefdeflong

Type Bool

Default value No

Description Undocumented.

Pairgridlowerangularorder

Type Integer

Default value 5

Description Undocumented.

Pairgridradpointsincrease

Type Integer

Default value 0

Description Undocumented.

Renormalizechargefitrho0

Type Bool

Default value No

Description Undocumented.

Shiftmultipoleorigin

Type Bool

Default value Yes

Description Undocumented.

Skipinlgwsmodule

Type Bool

Default value Yes

Description Undocumented.

SubtractAtomicXC

Type Bool

Default value Yes

Description Derive stress from xc energy difference of molecule versus atoms.

Usesymmetry

Type Bool

Default value No

Description Undocumented.

Usevstrainderrho

Type Bool

Default value No

Description Undocumented.

fitrho0numintextral

> **Type** Integer
>
> **Default value** 0
>
> **Description** Undocumented.

SubSymmetry

> **Type** Integer List
>
> **Description** The indices of the symmetry operators to maintain.

Tails

> **Type** Block
>
> **Description** Ignore function tails.

> **Bas**
>
> > **Type** Float
> >
> > **Default value** 1e-06
> >
> > **GUI name** Basis functions
> >
> > **Description** Cut off the basis functions when smaller than the specified threshold.

Title

> **Type** String
>
> **Default value**
>
> **Description** Title of the calculation, which will be printed in the output file.

Unrestricted

> **Type** Bool
>
> **Default value** No
>
> **Description** Controls whether Band should perform a spin-unrestricted calculation. Spin-unrestricted calculations are computationally roughly twice as expensive as spin-restricted.

UnrestrictedOnlyReference

> **Type** Bool
>
> **Default value** No
>
> **Description** Undocumented.

UnrestrictedReference

> **Type** Bool
>
> **Default value** No
>
> **Description** Undocumented.

UnrestrictedStartup

> **Type** Bool
>
> **Default value** No
>
> **Description** Undocumented.

UseInversionSymmetryInReciprocalSpace

Type Bool

Default value Yes

Description Whether to use inversion symmetry in reciprocal space. This is almost always a valid assumption.

UseSymmetry

Type Bool

Default value Yes

Description Whether or not to exploit symmetry during the calculation.

XC

Type Block

Description Exchange Correlation functionals

DFTHalf

Type Block

Description DFT-1/2 method for band gaps. See PRB vol 78,125116 2008. This method can be used in combination with any functional. For each active atom type (see ActiveAtomType) Band will perform SCF calculations at different screening cut-off values (see ScreeningCutOffs) and pick the cut-off value that maximizes the band gap. If multiple atom types are active, the screening cut-off optimizations are done one type at the time (in the same order as the ActiveAtomType blocks appear in the input).

ActiveAtomType

Type Block

Recurring True

Description Use the DFT-1/2 method for the atom-type specified in this block.

AtomType

Type String

Description Atom-type to use. You can activate all atom-types by specifying 'All'.

IonicCharge

Type Float

Default value 0.5

Description The amount of charge to be removed from the atomic HOMO.

ScreeningCutOffs

Type Float List

Default value [0.0, 1.0, 2.0, 3.0, 4.0, 5.0]

Unit Bohr

Description List of screening cut-offs (to screen the asymptotic IonicCharge/r potential). Band will loop over these values and find the cut-off that maximizes the band-gap. If only one number is provided, Band will simply use that value.

Enabled

Type Bool

> **Default value** No
>
> **GUI name** Use method
>
> **Description** Whether the DFT-1/2 method will be used.

Prepare

> **Type** Bool
>
> **Default value** No
>
> **Description** Analyze the band structure to determine reasonable settings for an DFT-1/2 calculation. If this is possible the list of active atom types is written to the output. This can be used in a next run as the values for ActiveAtomType. The DFTHalf%Enabled key should be set to false

SelfConsistent

> **Type** Bool
>
> **Default value** Yes
>
> **Description** Apply the extra potential during the SCF, or only afterwards. Applying DFT-1/2 only post SCF increases the band gap, compared to the self-consistent one.

DoubleHybrid

> **Type** String
>
> **Description** Specifies the double hybrid functional that should be used during the SCF.

EmpiricalScaling

> **Type** Multiple Choice
>
> **Default value** None
>
> **Options** [None, SOS, SCS, SCSMI]
>
> **Description** Calculate the (SOS/SCS/SCSMI)-MP2 correlation energy.

GLLBKParameter

> **Type** Float
>
> **Default value** 0.382
>
> **Description** K parameter for the GLLB functionals. See equation (20) of the paper.

HartreeFock

> **Type** Bool
>
> **Default value** No
>
> **Description** Stand alone HF calculation.

MP2

> **Type** Bool
>
> **Default value** No
>
> **Description** Calculate the MP2 correlation energy after the HF SCF is completed.

RPA

> **Type** Multiple Choice

> **Default value** None
>
> **Options** [None, Direct, Sigma, SOSEX, SOSSX]
>
> **Description** Specifies that RPA is used an possibly also a post-RPA method. By default, direct RPA is used

diracgga

> **Type** String
>
> **Default value**
>
> **Description** GGA for the dirac .

dispersion

> **Type** String
>
> **Default value** DEFAULT
>
> **Description** The dispersion correction model to be used.

gga

> **Type** String
>
> **Default value** NONE
>
> **Description** GGA XC functional.

lda

> **Type** String
>
> **Default value** VWN
>
> **Description** LDA XC functional.

libxc

> **Type** String
>
> **Default value** NONE
>
> **Description** Functional using the LicXC library.

libxcdensitythreshold

> **Type** Float
>
> **Default value** 1e-10
>
> **Description** Density threshold for LibXC functionals.

metagga

> **Type** String
>
> **Default value** NONE
>
> **Description** MetaGG XC functional.

model

> **Type** String
>
> **Default value** LB94
>
> **Description** Model potential. The possible choices are LB94, GLLB-SC, BGLLB-VWN, and BGLLB-LYP

spinorbitmagnetization

>	**Type** String

>	**Default value** collinearz

>	**Description** Type of Spin-Orbit magnetization.

tb_mbjafactor

>	**Type** Float

>	**Default value** -1.23456789

>	**Description** a parameter for the TB-MBJ model potential.

tb_mbjbfactor

>	**Type** Float

>	**Default value** -1.23456789

>	**Description** b parameter for the TB-MBJ model potential..

tb_mbjcfactor

>	**Type** Float

>	**Default value** -1.23456789

>	**Description** c parameter for the TB-MBJ model potential..

tb_mbjefactor

>	**Type** Float

>	**Default value** -1.23456789

>	**Description** e parameter for the TB-MBJ model potential..

usexcfun

>	**Type** Bool

>	**Default value** No

>	**Description** Whether ot not the XCFun library should be used.

xcfun

>	**Type** Bool

>	**Default value** No

>	**Description** Functional for the XCFun library.

ZlmFit

>	**Type** Block

>	**Description** Options for the density fitting scheme 'ZlmFit'.

AllowBoost

>	**Type** Bool

>	**Default value** Yes

>	**Description** Allow automatic atom-dependent tuning of maximum l of spherical harmonics expansion. Whether or not this boost is needed for a given atom is based on an heuristic estimate of how complex the density around that atom is.

DensityThreshold

> **Type** Float
>
> **Description** Threshold below which the electron density is considered to be negligible. Depends on Quality and is normally 1.0e-7

FGaussianW

> **Type** Float
>
> **Default value** 1.0
>
> **Description** Only for 3D periodic systems. Width of the Gaussian functions replacing the S and P Zlms for Fourier transform.

FGridSpacing

> **Type** Float
>
> **Description** Only for 3D periodic systems. Spacing for the Fourier grid. By default, this depends on the quality.

FKSpaceCutOff

> **Type** Float
>
> **Description** Only for 3D periodic systems. Cut-off of the grid in k-space for the Fourier transform.

FirstTopoCell

> **Type** Integer
>
> **Default value** 5
>
> **Description** First cell for the topological extrapolation of the long range part of the Coulomb Potential.

LMargin

> **Type** Integer
>
> **Description** User-defined l-margin, i.e., l_max for fitting is max(lMargin + l_max_basis_function, 2*l_max_basis_function). Depends on Quality and normally is 4

LastTopoCell

> **Type** Integer
>
> **Default value** 10
>
> **Description** Last cell for the topological extrapolation of the long range part of the Coulomb Potential.

NumStarsPartitionFun

> **Type** Integer
>
> **Default value** 5
>
> **Description** Number of cell stars to consider when computing the partition function.

OrderTopoTrick

> **Type** Integer
>
> **Default value** 3
>
> **Description** Order of the topological extrapolation of the long range part of the Coulomb Potential.

PartitionFunThreshold

>   **Type** Float

>   **Default value** 0.0

>   **Description** Threshold for the partition functions: if an integration point has a partition function weight smaller than this threshold, it will be discarded.

Quality

>   **Type** Multiple Choice

>   **Default value** Auto

>   **Options** [Auto, Basic, Normal, Good, VeryGood, Excellent]

>   **GUI name** Spline Zlm fit

>   **Description** Quality of the density-fitting approximation. For a description of the various qualities and the associated numerical accuracy see reference. If 'Auto', the quality defined in the 'NumericalQuality' will be used.

QualityPerRegion

>   **Type** Block

>   **Recurring** True

>   **Description** Sets the ZlmFit quality for all atoms in a region. If specified, this overwrites the globally set quality.

>   **Quality**

>>   **Type** Multiple Choice

>>   **Options** [Basic, Normal, Good, VeryGood, Excellent]

>>   **Description** The region's quality of the ZlmFit.

>   **Region**

>>   **Type** String

>>   **Description** The identifier of the region for which to set the quality.

12.2.2 conductance

KF OUTPUT FILES

13.1 Accessing KF files

KF files are Direct Access binary files. KF stands for Keyed File: KF files are keyword oriented, which makes them easy to process by simple procedures. Internally all the data on KF files is organized into sections containing variables, so each datum on the file can be identified by the combination of section and variable.

All KF files can be opened using the KFbrowser GUI program:

```
$AMSBIN/kfbrowser path/to/ams.rkf
```

By default KFbrowser shows a just a curated summary of the results on the file, but you can make it show the raw section and variable structure by switching it to expert mode. To do this, click on **File → Expert Mode** or press **ctrl/cmd + e**.

KF files can be opened and read with Command line tools.

For working with the data from KF files, it is often useful to be able to read them from Python. Using the AMS Python Stack, this can easily be done with the AKFReader class:

```
>>> from scm.akfreader import AKFReader
>>> kf = AKFReader("path/to/ams.rkf")
>>> "Molecule%Coords" in kf
True
>>> kf.description("Molecule%Coords")
{
    '_type': 'float_array',
    '_shape': [3, 'nAtoms'],
    '_comment': 'Coordinates of the nuclei (x,y,z)',
    '_unit': 'Bohr'
}
>>> kf.read("Molecule%Coords")
array([[-11.7770694 ,  -4.19739597,   0.04934546],
       [ -9.37471321,  -2.63234227,  -0.13448698],
        ...
       [ 10.09508738,  -1.06191208,   1.45286913],
       [ 10.11689333,  -1.5080196 ,  -1.87916127]])
```

Tip: For a full overview of the available methods in AKFReader, see the AKFReader API documentation.

13.2 Sections and variables on band.rkf

AMSResults **Section content:** Generic results of the BAND evaluation.

AMSResults%Bonds

      Type subsection

      Description Bond info

AMSResults%Bonds%Atoms

      Type archived_int_array

      Description ?

AMSResults%Bonds%CellShifts

      Type archived_int_array

      Description ?

AMSResults%Bonds%description

      Type string

      Description A string containing a description of how the bond orders were calculated / where they come from

AMSResults%Bonds%hasCellShifts

      Type bool

      Description Whether there are cell shifts (relevant only in case of periodic boundary conditions)

AMSResults%Bonds%Index

      Type archived_int_array

      Description index(i) points to the first element of Atoms, Orders, and CellShifts belonging to bonds from atom 'i'. Index(1) is always 1, Index(nAtoms+1) is always nBonds + 1

AMSResults%Bonds%Orders

      Type archived_float_array

      Description The bond orders.

AMSResults%BulkModulus

      Type float

      Description The Bulk modulus (conversion factor from hartree/bohr^3 to GPa: 29421.026)

      Unit hartree/bohr^3

AMSResults%Charges

      Type float_array

      Description Net atomic charges as computed by the engine (for example, the Charges for a water molecule might be [-0.6, 0.3, 0.3]). The method used to compute these atomic charges depends on the engine.

      Unit e

      Shape [Molecule%nAtoms]

AMSResults%DipoleGradients

Type float_array

Description Derivative of the dipole moment with respect to nuclear displacements.

Shape [3, 3, Molecule%nAtoms]

AMSResults%DipoleMoment

Type float_array

Description Dipole moment vector (x,y,z)

Unit e*bohr

Shape [3]

AMSResults%ElasticTensor

Type float_array

Description The elastic tensor in Voigt notation (6x6 matrix for 3D periodic systems, 3x3 matrix for 2D periodic systems, 1x1 matrix for 1D periodic systems).

Unit hartree/bohr^nLatticeVectors

Shape [:, :]

AMSResults%Energy

Type float

Description The energy computed by the engine.

Unit hartree

AMSResults%fractionalOccupation

Type bool

Description Whether of not we have fractionally occupied orbitals (i.e. not all occupations are integer numbers).

AMSResults%Gradients

Type float_array

Description The nuclear gradients.

Unit hartree/bohr

Shape [3, Molecule%nAtoms]

AMSResults%Hessian

Type float_array

Description The Hessian matrix

Unit hartree/bohr^2

Shape [3*Molecule%nAtoms, 3*Molecule%nAtoms]

AMSResults%HOMOEnergy

Type float_array

Description Molecular Orbital Info: energy of the HOMO.

Unit hartree

Shape [nSpin]

AMSResults%HOMOIndex

> **Type** int_array
>
> **Description** Molecular Orbital Info: index in the arrays orbitalEnergies and orbitalOccupations corresponding to the HOMO.
>
> **Shape** [nSpin]

AMSResults%HOMOLUMOGap

> **Type** float_array
>
> **Description** Molecular Orbital Info: HOMO-LUMO gap per spin.
>
> **Unit** hartree
>
> **Shape** [nSpin]

AMSResults%LUMOEnergy

> **Type** float_array
>
> **Description** Molecular Orbital Info: energy of the LUMO.
>
> **Unit** hartree
>
> **Shape** [nSpin]

AMSResults%LUMOIndex

> **Type** int_array
>
> **Description** Molecular Orbital Info: index in the arrays orbitalEnergies and orbitalOccupations corresponding to the LUMO.
>
> **Shape** [nSpin]

AMSResults%Molecules

> **Type** subsection
>
> **Description** Molecules

AMSResults%Molecules%AtCount

> **Type** archived_int_array
>
> **Description** shape=(nMolType), Summary: number of atoms per formula.

AMSResults%Molecules%Atoms

> **Type** archived_int_array
>
> **Description** shape=(nAtoms), atoms(index(i):index(i+1)-1) = atom indices of molecule i

AMSResults%Molecules%Count

> **Type** archived_int_array
>
> **Description** Mol count per formula.

AMSResults%Molecules%Formulas

> **Type** string
>
> **Description** Summary: unique molecule formulas

AMSResults%Molecules%Index

> **Type** archived_int_array

Description shape=(nMol+1), index(i) = index of the first atom of molecule i in array atoms(:)

AMSResults%Molecules%Type

    Type archived_int_array

    Description shape=(nMol), type of the molecule, reference to the summary arrays below

AMSResults%nOrbitals

    Type int

    Description Molecular Orbital Info: number of orbitals.

AMSResults%nSpin

    Type int

    Description Molecular Orbital Info: number spins (1: spin-restricted or spin-orbit coupling, 2: spin unrestricted).

AMSResults%orbitalEnergies

    Type float_array

    Description Molecular Orbital Info: the orbital energies.

    Unit hartree

    Shape [nOrbitals, nSpin]

AMSResults%orbitalOccupations

    Type float_array

    Description Molecular Orbital Info: the orbital occupation numbers. For spin restricted calculations, the value will be between 0 and 2. For spin unrestricted or spin-orbit coupling the values will be between 0 and 1.

    Shape [nOrbitals, nSpin]

AMSResults%PESPointCharacter

    Type string

    Description The character of a PES point.

    Possible values ['local minimum', 'transition state', 'stationary point with >1 negative frequencies', 'non-stationary point']

AMSResults%PoissonRatio

    Type float

    Description The Poisson ratio

AMSResults%ShearModulus

    Type float

    Description The Shear modulus (conversion factor from hartree/bohr^3 to GPa: 29421.026)

    Unit hartree/bohr^3

AMSResults%SmallestHOMOLUMOGap

    Type float

    Description Molecular Orbital Info: the smallest HOMO-LUMO gap irrespective of spin (i.e. min(LUMO) - max(HOMO)).

> > **Unit** hartree

> **AMSResults%StressTensor**

> > **Type** float_array

> > **Description** The clamped-ion stress tensor in Cartesian notation.

> > **Unit** hartree/bohr^nLatticeVectors

> > **Shape** [:, :]

> **AMSResults%YoungModulus**

> > **Type** float

> > **Description** The Young modulus (conversion factor from hartree/bohr^3 to GPa: 29421.026)

> > **Unit** hartree/bohr^3

AngularBoost **Section content:** Both the Becke grid and the Zlm fit grid may boost the angular grid for certain areas.

> **AngularBoost%boost**

> > **Type** bool_array

> > **Description** Whether to use a booster grid per atom.

band_curves **Section content:** Band dispersion curves.

> **band_curves%brav_type**

> > **Type** string

> > **Description** Type of the lattice.

> **band_curves%Edge_#_bands**

> > **Type** float_array

> > **Description** The band energies

> > **Shape** [nBands, nSpin, :]

> **band_curves%Edge_#_direction**

> > **Type** float_array

> > **Description** Direction vector.

> > **Shape** [nDimK]

> **band_curves%Edge_#_fatBands**

> > **Type** float_array

> > **Description** Fat band split up of the bands

> > **Shape** [nBas, nBands, nSpin, :]

> **band_curves%Edge_#_kPoints**

> > **Type** float_array

> > **Description** Coordinates for points along the edge.

> > **Shape** [nDimK, :]

> **band_curves%Edge_#_labels**

> > **Type** lchar_string_array

Description Labels for begin and end point of the edge.

Shape [2]

band_curves%Edge_#_lGamma

Type bool

Description Is gamma point?

band_curves%Edge_#_nKPoints

Type int

Description The nr. of k points along the edge.

band_curves%Edge_#_vertices

Type float_array

Description Begin and end point of the edge.

Shape [nDimK, 2]

band_curves%Edge_#_xFor1DPlotting

Type float_array

Description x Coordinate for points along the edge.

Shape [:]

band_curves%indexLowestBand

Type int

Description ?

band_curves%nBands

Type int

Description Number of bands.

band_curves%nBas

Type int

Description Number of basis functions.

band_curves%nDimK

Type int

Description Dimenion of the reciprocal space.

band_curves%nEdges

Type int

Description The number of edges. An edge is a line-segment through k-space. It has a begin and end point and possilby points in between.

band_curves%nEdgesInPath

Type int

Description A path is built up from a number of edges.

band_curves%nSpin

Type int

Description Number of spin components.

Possible values [1, 2]

band_curves%path

Type int_array

Description If the (edge) index is negative it means that the vertices of the edge abs(index) are swapped e.g. path = (1,2,3,0,-3,-2,-1) goes though edges 1,2,3, then there's a jump, and then it goes back.

Shape [nEdgesInPath]

band_curves%path_type

Type string

Description ?

BandStructure **Section content:** Info regarding the band structure…

BandStructure%BandGap

Type float

Description The band gap. For molecules this is the HOMO-LUMO gap.

Unit hartree

BandStructure%bandsEnergyRange

Type float_array

Description The energy ranges (min/max) of the bands

Unit hartree

Shape [2, nBand, nSpin]

BandStructure%BottomConductionBand

Type float

Description The bottom of the conduction band

Unit hartree

BandStructure%CoordsBottomConductionBand

Type float_array

Description The coordinates in k-space of the bottom of the conduction band

Unit 1/bohr

Shape [nDimK]

BandStructure%CoordsTopValenceBand

Type float_array

Description The coordinates in k-space of the top of the valence band

Unit 1/bohr

Shape [nDimK]

BandStructure%DerivativeDiscontinuity

Type float

Description Correction to be added to the band gap to get the fundamental gap. (band only)

Unit hartree

BandStructure%FermiEnergy

> **Type** float
>
> **Description** Fermi level
>
> **Unit** hartree

BandStructure%HasGap

basis%valence functions/part

Type int_array

Description Number of valence functions per part.

Shape [number of parts]

basis%valence functions/type

Type int_array

Description Number of valence functions per type.

Shape [geometry%ntyp]

basis%valence_labels

Type lchar_string_array

Description Labels for the valence functions.

Shape [ncores]

BeckeGridConfig Section content: Configuration used to create the Becke grid.

BeckeGridConfig%angLOrder

Type int_array

Description ?.

Shape [:]

BeckeGridConfig%beckeMapParams

Type float_array

Description Mapping parameter per atom.

Shape [nAtoms]

BeckeGridConfig%includeRadialWeights

Type bool

Description Whether or not to include the radial weights. Normally you want this.

BeckeGridConfig%isSymmetryUnique

Type bool_array

Description Is an atom symmetry unique?

Shape [nAtoms]

BeckeGridConfig%minimumRadius

Type float

Description To solve the exact singularity a small hard sphere around the nuclei can be used. The partition function starts beyond this radius.

BeckeGridConfig%mpvPartitionCheckSpheres

Type bool

Description Whether or not to check the spheres for the MPV partitioning.

BeckeGridConfig%nAtoms

Type int

>> **Description** Number of atoms.

BeckeGridConfig%nRadPoints

>> **Type** int_array

> > **Description** All 14 hardcoded bond energies in an array.

> > **Unit** hartree

> > **Shape** [14]

> **Bond energies%Becke (alt)**

> > **Type** float

Description Bond energy according to the Becke (alt) functional.

Unit hartree

Bond energies%Becke88

Type float

Description Bond energy according to the Becke88 (exchange) functional.

Unit hartree

Bond energies%Becke88+LYP

Type float

Description Bond energy according to the Becke88+LYP functional.

Unit hartree

Bond energies%Becke88+Perdew86

Type float

Description Bond energy according to the Becke88 plus Perdew86 (XC) functional.

Unit hartree

Bond energies%EV93x+PW91c

Type float

Description Bond energy according to the EV93x+PW91c functional.

Unit hartree

Bond energies%final bond energy

Type float

Description Bond energy according to the functional used during the SCF.

Unit hartree

Bond energies%LDA

Type float

Description Bond energy according to the LDA functional.

Unit hartree

Bond energies%PBE

Type float

Description Bond energy according to the PBE functional.

Unit hartree

Bond energies%PBESOL

Type float

Description Bond energy according to the PBESOL functional.

Unit hartree

Bond energies%Perdew-Wang (91) X

Type float

Description Bond energy according to the Perdew-Wang (91) (exchange) functional.

Unit hartree

Bond energies%Perdew-Wang (91) X+C

Type float

Description Bond energy according to the Perdew-Wang (91) X+C functional.

Unit hartree

Bond energies%PW86x+Perdew86c

Type float

Description Bond energy according to the PW86x+Perdew86c functional.

Unit hartree

Bond energies%RGE2

Type float

Description Bond energy according to the RGE2 functional.

Unit hartree

Bond energies%RPBE

Type float

Description Bond energy according to the RPBE functional.

Unit hartree

Bond energies%SELF-CONSISTENT

Type float

Description Bond energy according to the functional used during the SCF, in case that it is different from the final bond energy.

Unit hartree

> **Shape** [nband, nspin, kspace%kuniqu]

eigensystem%eMinMax

> **Type** float_array

Description Minimum and maximum for all bands.

Shape [2, nband, nspin]

eigensystem%hubbardOccupations

Type float_array

Description Occupations for the hubbard model.

Shape [SystType%nbas, SystType%nspin]

eigensystem%isHubbardOrb

Type bool_array

Description Whether an orbital is active in the Hubbard model.

Shape [SystType%nbas]

eigensystem%nband

Type int

Description Number of stored bands. This is smaller than or equal to the number of valence basis functions.

eigensystem%nband_occ

Type int

Description Number of bands with non zero occupations.

eigensystem%nspin

Type int

Description Number of spin components

Possible values [1, 2]

eigensystem%occful

Type float_array

Description Occupation numbers for full bands in all k-points. Second component only used when nspin=2

Shape [kspace%kt, 2]

eigensystem%occup

Type float_array

Description Occupation numbers for the bands in all unique k-points.

Shape [nband_occ, nspin, kspace%kuniqu]

eigensystem%occupationPerBandAndSpin

Type float_array

Description Occupations per band and spin.

Shape [nband, nspin]

eigensystem%PEDAocc

Type float_array

Description Occupations to be used.

`eigensystem%T(VOC/FOC3)`

> **Type** float_array
>
> **Description** Transformation (real/imag) from the VOC to the final fragment basis (FOC3). Does not allow for nspin=2.
>
> **Shape** [SystType%nbas, SystType%nbas, 2, kspace%kuniqu]

ElectrostaticEmbeddingType Section content: Electrostatic embedding.

`ElectrostaticEmbeddingType%eeAttachTo`

> **Type** int_array
>
> **Description** A multipole may be attached to an atom. This influences the energy gradient.

`ElectrostaticEmbeddingType%eeChargeWidth`

> **Type** float
>
> **Description** If charge broadening was used for external charges, this represents the width of the charge distribution.

`ElectrostaticEmbeddingType%eeEField`

> **Type** float_array
>
> **Description** The external homogeneous electric field.
>

`ElectrostaticEmbeddingType%eeNLatticeVectors`

> **Type** int
>
> **Description** The number of lattice vectors for the external point- or multipole- charges.

`ElectrostaticEmbeddingType%eeNMulti`

> **Type** int
>
> **Description** The number of external point- or multipole- charges.

`ElectrostaticEmbeddingType%eeNZlm`

> **Type** int

Description When external point- or multipole- charges are used, this represents the number of spherical harmonic components. E.g. if only point charges were used, eeNZlm=1 (s-component only). If point charges and dipole moments were used, eeNZlm=4 (s, px, py and pz).

ElectrostaticEmbeddingType%eeUseChargeBroadening

    Type bool

    Description Whether or not the external charges are point-like or broadened.

ElectrostaticEmbeddingType%eeXYZ

    Type float_array

    Description The position of the external point- or multipole- charges.

    Unit bohr

    Shape [3, eeNMulti]

Energy gradients Section content: Various terms contributing to the energy gradients.

Energy gradients%Cosmo

    Type float_array

    Description COSMO solvation energy contribution to the gradients (at fixed density matrix).

    Unit hartree/bohr

    Shape [3, Molecule%nAtoms]

Energy gradients%Dispersion

    Type float_array

    Description Empirical dispersion energy contribution to the gradients (at fixed density matrix).

    Unit hartree/bohr

    Shape [3, Molecule%nAtoms]

Energy gradients%Electric field

    Type float_array

    Description External electric field contribution to the gradients (at fixed density matrix).

    Unit hartree/bohr

    Shape [3, Molecule%nAtoms]

Energy gradients%Electrostatic energy

    Type float_array

    Description Non-pair electrostatic energy contribution to the gradients (at fixed density matrix).

    Unit hartree/bohr

    Shape [3, Molecule%nAtoms]

Energy gradients%Kinetic energy

    Type float_array

    Description Kintetic energy contribution to the gradients (at fixed density matrix).

    Unit hartree/bohr

    Shape [3, Molecule%nAtoms]

Energy gradients%P Matrix

Type float_array

Description Density matrix contribution to the gradients (pulay term).

Unit hartree/bohr

Shape [3, Molecule%nAtoms]

Energy gradients%Pair interactions

Type float_array

Description Electrostatic pair energy contribution to the gradients. Follows from purely spherical pair contributions.

Unit hartree/bohr

Shape [3, Molecule%nAtoms]

Energy gradients%Total

Type float_array

Description Total energy gradients.

Unit hartree/bohr

Shape [3, Molecule%nAtoms]

Energy gradients%XC energy

Type float_array

Description XC energy contribution to the gradients (at fixed density matrix).

Unit hartree/bohr

Shape [3, Molecule%nAtoms]

Energy stress tensor **Section content:** The stress tensor is the energy derivative with respect to strains, divided by the volume. They can and are obtained from energy derivatives along symmetric strain modes.

Energy stress tensor%a1LatticeStrains

Type float_array

Description Totally symmetric strains.

Unit bohr

Shape [Molecule%nLatticeVectors, Molecule%nLatticeVectors, nA1LatticeStrains]

Energy stress tensor%at def

Type float_array

Description At-def energy contribution to the stress tensor.

Unit a.u.

Shape [Molecule%nLatticeVectors, Molecule%nLatticeVectors]

Energy stress tensor%at def(modeSD)

Type float_array

Description At-def contribution to the symmetric strain mode derivatives.

Unit a.u.

Shape [nA1LatticeStrains]

> **Shape** [3, nfrag, SystType%nspin, kspace%kuniqu]

FuzzyUnitCell **Section content:** Becke-style unit cell partition function.

FuzzyUnitCell%CoordsFuzzyAtoms

> **Type** float_array
>
> **Description** Coordinates of the atoms inside the region where the fuzzy unit cell is not zero.
>
> **Shape** [3, nFuzzyAtoms]

FuzzyUnitCell%nCells

> **Type** int
>
> **Description** Number of cells needed for a fuzzy cell summation.

FuzzyUnitCell%nFuzzyAtoms

> **Type** int
>
> **Description** Number of atoms inside the region where the fuzzy unit cell is not zero.

FuzzyUnitCell%PartitionFunctionOnAtoms

> **Type** float_array
>
> **Description** Value of the partition function at the atomic positions.
>
> **Shape** [nFuzzyAtoms]

FuzzyUnitCell%qFuzzyAtoms

> **Type** float_array
>
> **Description** Nuclear charges (atom number) of the atoms inside the region where the fuzzy unit cell is not zero.
>
> **Shape** [nFuzzyAtoms]

FuzzyUnitCell%UnitCellAtomIndex

Type int_array

Description Cell index for all the fuzzy atoms.

Shape [nFuzzyAtoms]

FuzzyUnitCell%xyzCells

Type float_array

Description Coordinates of the cells needed for the fuzzy cell summation.

Shape [3, nCells]

General Section content: General information about the BAND calculation.

General%account

Type string

Description Name of the account from the license

General%engine input

Type string

Description The text input of the engine.

General%engine messages

Type string

Description Message from the engine. In case the engine fails to solves, this may contains extra information on why.

General%file-ident

Type string

Description The file type identifier, e.g. RKF, RUNKF, TAPE21…

General%jobid

Type int

Description Unique identifier for the job.

General%program

Type string

Description The name of the program/engine that generated this kf file.

General%release

Type string

Description The version of the program that generated this kf file (including svn revision number and date).

General%termination status

Type string

Description The termination status. Possible values: 'NORMAL TERMINATION', 'NORMAL TERMINATION with warnings', 'NORMAL TERMINATION with errors', 'ERROR', 'IN PROGRESS'.

General%title

> **Type** string
>
> **Description** Title of the calculation.

General%uid

> **Type** string
>
> **Description** SCM User ID

General%version

> **Type** int
>
> **Description** Version number?

geometry Section content: Information on the geometry.

geometry%Atom map new order

> **Type** int_array
>
> **Description** From input to internal: internalAtomIndex = array(inputAtomIndex).
>
> **Shape** [natomt]

geometry%Atom map old order

> **Type** int_array
>
> **Description** From internal to input: inputAtomIndex = array(internalAtomIndex).
>
> **Shape** [natomt]

geometry%atomTypeString

> **Type** lchar_string_array
>
> **Description** ?.
>
> **Shape** [Molecule%nAtoms]

geometry%distances(atom sets)

> **Type** float_array
>
> **Description** Half matrix containing distances between atom sets.

geometry%input_lattice

> **Type** float_array
>
> **Description** The lattice vectors (if any) as specified on input.
>
> **Unit** bohr
>
> **Shape** [3, 3]

geometry%input_xyzatm

> **Type** float_array
>
> **Description** The coordinates of the atoms as specified on input.
>
> **Unit** bohr
>
> **Shape** [3, natomt]

geometry%itypat

> **Type** int_array

Description The type in the range [1:ntyp] for all atoms.

Shape [natomt]

geometry%mdim

Type int

Description Dimension of the molecule, i.e. 1 for somting linear, 2 for a flat one.

geometry%natom

Type int_array

Description For each set the number of atoms.

Shape [natstt]

geometry%natomt

Type int

Description Number of atoms.

geometry%natst

Type int_array

Description Number of atom sets for all types.

Shape [ntyp]

geometry%natstt

Type int

Description Number of atom sets. A set consists of symmetry equivalent atoms.

geometry%ntyp

Type int

Description Number of types, i.e. atoms with a different basis set, or accuracy setting (or different region).

geometry%Number of selected atoms

Type int

Description Number of selected atoms.

geometry%qatm

Type float_array

Description Charge of the nuclei (almost always the atomic number).

Shape [ntyp]

geometry%qelec

Type float

Description The number of valence electrons (not including a nett charge of the system).

geometry%qset

Type float_array

Description Valence charge per atom set.

> > **Shape** [natstt]

> **geometry%removeZSymmetry**

> > **Type** bool

> > **Description** Remove z symmetry from the symmetry operator set.

> **geometry%Selected atoms (input order)**

> > **Type** int_array

> > **Description** List of selcted atoms.

> > **Shape** [Number of selected atoms]

> **geometry%standard_lattice**

> > **Type** float_array

> > **Description** The lattice vectors (if any) in the standard frame.

> > **Unit** bohr

> > **Shape** [3, 3]

> **geometry%standard_xyzatm**

> > **Type** float_array

> > **Description** The coordinates of the atoms after transforming to the standard frame.

> > **Unit** bohr

> > **Shape** [3, natomt]

> **geometry%xyzatm(atoms_in_new_order)**

> > **Type** float_array

> > **Description** The coordinates of the atoms in the internal order.

> > **Unit** bohr

> > **Shape** [3, natomt]

GeomType **Section content:** Geometry related info.

> **GeomType%avec**

> > **Type** float_array

> > **Description** The lattice stored as a 3xnLatticeVectors matrix. Only the ndimk,ndimk part has meaning.

> > **Unit** bohr

> > **Shape** [kspace%ndim, kspace%ndim]

> **GeomType%bvec**

> > **Type** float_array

> > **Description** The inverse lattice stored as a 3x3 matrix. Only the ndimk,ndimk part has meaning.

> > **Unit** 1/bohr

> > **Shape** [kspace%ndim, kspace%ndim]

> **GeomType%natomt**

Type int

Description Number of atoms. (Same as geometry%natomt)

GeomType%natstt

Type int

Description Number of atom sets. A set consists of symmetry equivalent atoms. (Same as geometry%natstt)

GeomType%ndim

Type int

Description Number of dimensions for the molecule. Water is flat and has two dimensions.

GeomType%ndimk

Type int

Description Number of dimensions for k-space integration. Normally this is the number of lattice vectors.

GeomType%noper

Type int

Description Number of symmetry operators (real space). (Same as Symmetry%Nr. of operators)

GeomType%noperk

Type int

Description Number of symmetry operators (reciprocal space). (Same as Symmetry Nr. of operators (k-space))

GeomType%ntyp

Type int

Description Number of types, i.e. atoms with a different basis set, or accuracy setting (or different region). (Same as geometry%ntyp)

GeomType%Serializer::type

Type string_fixed_length

Description Information for the Serializer code.

GeomType%stdrot

Type float_array

Description Rotation to the standard frame. The point group part (P) of x_standard = P x_input + t.

Shape [3, 3]

GeomType%stdvec

Type float_array

Description Translation to the standard frame. The translation part (t) of x_standard = P x_input + t.

Shape [3]

KFDefinitions **Section content:** The definitions of the data on this file

KFDefinitions%json

> **Type** string
>
> **Description** The definitions of the data on this file in json.

KPointsConfig **Section content:** Configuration information for the k-space integration points. This is all about splitting the space into simplices.

KPointsConfig%commentString

> **Type** string_fixed_length
>
> **Description** Description on how the grid was generated.

KPointsConfig%interpolation

> **Type** int
>
> **Description** How to interpolate the bands over the simplices. 1) linear method, 2) quadratic method.

KPointsConfig%method

> **Type** int
>
> **Description** Method used to divide space into simplices 1) symmetric method, 2) grid. The k-space integration method is the same.

KPointsConfig%ndimk

> **Type** int
>
> **Description** Dimension of reciprocal space.

KPointsConfig%parameters

> **Type** int_array
>
> **Description** For the symmetric method parameters(1) will be the accuracy parameter. For the regular method the parameters are per lattice vector.

Shape [3]

KPointsConfig%splitCubeInSix

    Type bool

    Description We want to split a cube in tetrahedra. The minimal number needed is five. With six it looks more symmetrical.

KPointsConfig%splitLongest

    Type bool

    Description Sometimes a tetrahedron needs to be split, and there is some arbitrariness in how to do that. With this option the longest edge will be used.

KPointsConfig%splitPermutation

    Type int_array

    Description There is some arbitrariness when splitting a volume. Also the order of the splitting has some effect.

KPointsConfig%symSampling

    Type bool

    Description Map out points from Irr. BZ of the pure lattice (neglecting atoms).

kspace Section content: Info regarding the k-space integration…

kspace%avec

    Type float_array

    Description The lattice stored as a 3xnLatticeVectors matrix. Only the ndimk,ndimk part has meaning.

    Unit bohr

    Shape [3, :]

kspace%bvec

    Type float_array

    Description The inverse lattice stored as a 3x3 matrix. Only the ndimk,ndimk part has meaning.

    Unit 1/bohr

    Shape [ndim, ndim]

kspace%bzvol

    Type float

    Description The volume of the BZ zone. In 2D it is the surface and in 1D it is the lenght. The unit is bohr raised to the power ndim.

kspace%iDimkEffective

    Type int_array

    Description Which latttice vectors are really used for the k-space integration.

    Shape [nDimkEffective]

kspace%isKunComplex

    Type bool_array

Description Whether or not the Hamiltonian matrix is complex for a unique k-point.

Shape [kuniqu]

kspace%kequiv

Type int_array

Description When kequiv(i)=i the k-point is unique.

Shape [kt]

kspace%kequn

Type int_array

Description When looping over all k-points, the unique index is kun=kequn(k).

Shape [kt]

kspace%kinteg

Type int

Description In case a symmetric grid is used this is the parameter used to create it.

kspace%klbl

Type lchar_string_array

Description labes describing the k-points

Shape [kt]

kspace%klblun

Type lchar_string_array

Description labes describing the unique k-points

Shape [kuniqu]

kspace%klnear

Type bool

Description Whether or not linear k-space integration is used (symmetric method with even kinteg).

kspace%ksimpl

Type int_array

Description Index array defining the simplices, refering to the xyzpt array.

Shape [nvertk, nsimpl]

kspace%kt

Type int

Description The total number of k-points used by the k-space to sample the unique wedge of the Brillouin zone.

kspace%ktBoltz

Type float

Description band only?.

kspace%kuniqu

Type int

Description The number of symmetry unique k-points where an explicit diagonalization is needed. Smaller or equal to kt.

kspace%ndim

Type int

Description The nr. of lattice vectors.

kspace%ndimk

Type int

Description The nr. of dimensions used in the k-space integration.

kspace%nDimkEffective

Type int

Description Normally ndimk is equal to the number of lattice vectors. For very large lattice vectors the k-space dispersion is ignored, leading to a lower dimensional band structure.

kspace%noperk

Type int

Description The nr. of operators in k-space. band only?

kspace%nsimpl

Type int

Description The number of simplices constructed from the k-points to span the IBZ.

kspace%numBoltz

Type int

Description Number of enegies to sample around the fermi energy. band only?

kspace%numEquivSimplices

Type int_array

Description Simplices may be equivalent due to symmetry operations..

Shape [nsimpl]

kspace%nvertk

Type int

Description The number of vertices that each simplex has.

kspace%operk

Type float_array

Description Symmetry operators in k-space. band only?

Unit bohr

Shape [ndim, ndim, noperk]

kspace%xyzpt

Type float_array

Description The coordinates of the k-points.

Unit 1/bohr

Shape [ndimk, kt]

kspace(primitive cell) **Section content:** should not be here!!!

      Type int_array

      Description Sizes of the blocks.

      Shape [Number of Blocks]

Molecule **Section content:** The input molecule of the calculation.

Molecule%AtomicNumbers

      Type int_array

      Description Atomic number 'Z' of the atoms in the system

      Shape [nAtoms]

Molecule%AtomMasses

      Type float_array

      Description Masses of the atoms

      Unit a.u.

      Values range [0, '\infinity']

      Shape [nAtoms]

Molecule%AtomSymbols

      Type string

      Description The atom's symbols (e.g. 'C' for carbon)

      Shape [nAtoms]

Molecule%bondOrders

      Type float_array

Description The bond orders for the bonds in the system. The indices of the two atoms partici-
pating in the bond are defined in the arrays 'fromAtoms' and 'toAtoms'. e.g. bondOrders[1]=2,
fromAtoms[1]=4 and toAtoms[1]=7 means that there is a double bond between atom number
4 and atom number 7

Molecule%Charge

    Type float

    Description Net charge of the system

    Unit e

Molecule%Coords

    Type float_array

    Description Coordinates of the nuclei (x,y,z)

    Unit bohr

    Shape [3, nAtoms]

Molecule%eeAttachTo

    Type int_array

    Description A multipole may be attached to an atom. This influences the energy gradient.

Molecule%eeChargeWidth

    Type float

    Description If charge broadening was used for external charges, this represents the width of the
charge distribution.

Molecule%eeEField

    Type float_array

    Description The external homogeneous electric field.

    Unit hartree/(e*bohr)

    Shape [3]

Molecule%eeLatticeVectors

    Type float_array

    Description The lattice vectors used for the external point- or multipole- charges.

    Unit bohr

    Shape [3, eeNLatticeVectors]

Molecule%eeMulti

    Type float_array

    Description The values of the external point- or multipole- charges.

    Unit a.u.

    Shape [eeNZlm, eeNMulti]

Molecule%eeNLatticeVectors

    Type int

Description The number of lattice vectors for the external point- or multipole- charges.

Molecule%eeNMulti

> **Type** int
>
> **Description** The number of external point- or multipole- charges.

Molecule%eeNZlm

> **Type** int
>
> **Description** When external point- or multipole- charges are used, this represents the number of spherical harmonic components. E.g. if only point charges were used, eeNZlm=1 (s-component only). If point charges and dipole moments were used, eeNZlm=4 (s, px, py and pz).

Molecule%eeUseChargeBroadening

> **Type** bool
>

NAOSetCells **Section content:** For periodic systems neighboring cells need to be considered. More cells are needed for more diffuse basis sets.

NAOSetCells%Coords(#{entry})

        Type float_array

        Description Cell coordinates for a basis set.

        Shape [3, nCells(#{entry})]

NAOSetCells%Name(#{entry})

        Type string

        Description The name of the basis set.

NAOSetCells%nAtoms(#{entry})

        Type int

        Description Number of atoms for a basis set.

NAOSetCells%nCells(#{entry})

        Type int

        Description Number of cells needed for a basis set.

NAOSetCells%nEntries

        Type int

Description The number of entries (basis sets), for basis sets like valence and core, fit, etc..

`NAOSetCells%SkipAtom(#{entry})`

    Type bool_array

    Description Sometimes the functions of an atom do not require a cell at all.

    Shape [nAtoms(#{entry}), nCells(#{entry})]

NEGF Section content: NEGF models the electron transport through a device.

`NEGF%ContactShift`

    Type float

    Description ?

`NEGF%current`

    Type float_array

    Description Current from one contact to the other.

    Shape [nSpin]

`NEGF%DeltaPhi0`

    Type float

    Description To do with the alignment.

`NEGF%DeltaPhi1`

    Type float

    Description To do with the alignment of the potential to the bulk potential.

`NEGF%dos`

    Type float_array

    Description Density of states.

    Shape [nEnergies, nSpin]

`NEGF%energyGrid`

    Type float_array

    Description Energies for the NEGF results.

    Shape [nEnergies]

`NEGF%nEnergies`

    Type int

    Description Number of energies

`NEGF%nSpin`

    Type int

    Description Number of spin components.

`NEGF%OffsetShift`

    Type float

    Description ?

NEGF%transmission

>   **Type** float_array

>   **Description** Transmission.

>   **Shape** [nEnergies, nSpin]

NeutralizingDensity Section content: For charged (periodic) cells a neutralinng density is used.

NeutralizingDensity%neutralizingFactor

>   **Type** float

>   **Description** The fixed neutralizing density needs to be multiplied with this factor to make the system neutral (after adding it).

Num Int Params Section content: Parameters needed for the Voronoi grid. It is tried to integrate a set of functions up to a certain accuracy.

Num Int Params%accint

>   **Type** float

>   **Description** Desired accuracy thought of as 10**(-accint).

Num Int Params%accout

>   **Type** float

>   **Description** Setting of the accint parameter for the outer region.

Num Int Params%accpyr

>   **Type** float

>   **Description** Setting of the accint parameter for the pyramids.

Num Int Params%accsph

>   **Type** float

>   **Description** Setting of the accint parameter for the spheres.

Num Int Params%alfas

>   **Type** float_array

>   **Description** Exponents to use for the test functions. Per (radial) order a minimum and maximum alpha is given.

>   **Shape** [npowx, 2, ntyps]

Num Int Params%ldim

>   **Type** int

>   **Description** Number of lattice vectors.

Num Int Params%linteg all

>   **Type** int_array

>   **Description** Per element the l-value to integrate.

>   **Shape** [ntyps]

Num Int Params%lintgx

>   **Type** int

Description Maximum l-value to integrate.

Num Int Params%nnucs

> **Type** int
>
> **Description** Number of atoms, possibly including point charges.

Num Int Params%noper

> **Type** int
>
> **Description** Number of symmetry operators.

Num Int Params%npowx

> **Type** int
>
> **Description** The radial part of a STO test function will be tried up to this power?

Num Int Params%nratst1

> **Type** int_array
>
> **Description** Index array. nratst1(ityp) will be the first atom of that type.
>
> **Shape** [ntyps+1]

Num Int Params%ntyps

> **Type** int
>
> **Description** Number of non equivalent atoms (either by atomic number or basis set).

Num Int Params%oper

> **Type** float_array
>
> **Description** Point group part of the symmetry operators.
>
> **Shape** [3, 3, noper]

Num Int Params%qatm

> **Type** float_array
>
> **Description** Atomic numbers.
>
> **Shape** [ntyps]

Num Int Params%sphgrid

> **Type** bool_array
>
> **Description** For point charges in xyzatm some may not need a spherical grid when far away.
>
> **Shape** [nnucs]

Num Int Params%transl

> **Type** float_array
>
> **Description** Translational part of the symmetry operators (for periodic systems).
>
> **Shape** [3, noper]

Num Int Params%vlatt

> **Type** float_array
>
> **Description** Lattice vectors.

> **Unit** bohr
>
> **Shape** [3, ldim]

Num Int Params%xyzatm

> **Type** float_array
>
> **Description** Atomic coordinates.
>
> **Unit** bohr
>
> **Shape** [3, nnucs]

NumericalBasisSets Section content: Specification of numerical atomic basis sets, consisting of a numerical radial table and a spherical harmonic: R_{nl} Y_{lm}.

NumericalBasisSets%BasisType(#{set},#{type})

> **Type** string
>
> **Description** Something like valence or core for (type,set). Will not depend on type.

NumericalBasisSets%bField for GIAO(#{set},#{type})

> **Type** float_array
>
> **Description** Band only. Finite magnetic field strenght for GIAOs.
>
> **Shape** [3]

NumericalBasisSets%d2RadialFuncs(#{set},#{type})

> **Type** float_array
>
> **Description** The second derivative of the radial functions (for a type,set).
>
> **Shape** [NumRad(#{type}), nRadialFuncs(#{set},#{type})]

NumericalBasisSets%dRadialFuncs(#{set},#{type})

> **Type** float_array
>
> **Description** The derivative of the radial functions (for a type,set).
>
> **Shape** [NumRad(#{type}), nRadialFuncs(#{set},#{type})]

NumericalBasisSets%Element(#{type})

> **Type** string
>
> **Description** The chemcial element (H,He,Li) for a type.

NumericalBasisSets%GridType(#{type})

> **Type** string
>
> **Description** What kind of radial grid is used. Currently this is always logarithmic.

NumericalBasisSets%ljValues(#{set},#{type})

> **Type** int_array
>
> **Description** Normally for each radial function the l value. In case of spin-orbit there is also a j value (for a type,set).
>
> **Shape** [2, nRadialFuncs(#{set},#{type})]

NumericalBasisSets%MaxRad(#{type})

> **Type** float

> **Description** Maximum value of the radial grid (for a type).

NumericalBasisSets%MinRad(#{type})

> **Type** float

> **Description** Minimum value of the radial grid (for a type).

NumericalBasisSets%nRadialFuncs(#{set},#{type})

> **Type** int

> **Description** The number of radial functions (for a type,set).

NumericalBasisSets%nSets

> **Type** int

> **Description** The number of basis sets stored for each type. For instance if you store core and the valence basis sets it is two.

NumericalBasisSets%nTypes

> **Type** int

> **Description** The number of types: elements with a different basis set. Normally this is just the number of distinct elements in the sytem.

NumericalBasisSets%NumRad(#{type})

> **Type** int

> **Description** The number of radial points (for a type).

NumericalBasisSets%RadialFuncs(#{set},#{type})

> **Type** float_array

> **Description** The radial functions (for a type,set).

> **Shape** [NumRad(#{type}), nRadialFuncs(#{set},#{type})]

NumericalBasisSets%RadialMetaInfo(#{set},#{type})

> **Type** float_array

> **Description** Info about the radial functions. Whether it is a NAO or STO. For instance for an STO the alpha value. All encoded in a real array of fixed size.

> **Shape** [:, nRadialFuncs(#{set},#{type})]

NumericalBasisSets%SpherHarmonicType(#{set},#{type})

> **Type** string

> **Description** Either zlm or spinor (type,set). Will not depend on type.

NumiType Section content: Information related to numerical integration.

NumiType%accint

> **Type** float

> **Description** Accuracy parameter for the (obsolete) Voronoi grid.

NumiType%bzvol

> **Type** float

Description Volume of the Brillouin zone. In lower than 3D this is a surface (2D) or lenght (1D). For molecules it is set to one.

NumiType%kgrp

> **Type** int

> **Description** Number of k-points processed together.

NumiType%kinteg

> **Type** int

> **Description** K-space parameter used in case of the symmetric grid.

NumiType%kmesh

> **Type** int

> **Description** Parameter for the hybrid metod. The quadratic bands are integrated linearly on a grid that is finer by a factor kmesh. (seems obsolete)

NumiType%kt

> **Type** int

> **Description** Number of k-points.

NumiType%kuniqu

> **Type** int

> **Description** Number of unique k-points.

NumiType%nblock

> **Type** int

> **Description** Number of integration blocks.

NumiType%npx

> **Type** int

> **Description** Block size.

NumiType%npxsym

> **Type** int

> **Description** Obsolete.

NumiType%nrx

> **Type** int

> **Description** Maximum number of radial points (see the radial section).

NumiType%nsimpl

> **Type** int

> **Description** Number of simplices used for the irreducible Brillouin zone.

NumiType%nuelst

> **Type** int

> **Description** Parameter for elliptical grid used to calculate the electrostatic interaction between spherical densities.

NumiType%nvelst

> **Type** int
>
> **Description** Parameter for elliptical grid used to calculate the electrostatic interaction between spherical densities.

NumiType%nvertk

> **Type** int
>
> **Description** Number of vertices per simplex (k-space integration).

NumiType%Serializer::type

> **Type** string_fixed_length
>
> **Description** Information for the Serializer code.

NumiType%volnum

> **Type** float
>
> **Description** Sum of the weight of the real space grid. This only converges with better grids for 3d systems. Otherwise is simply grows with grid size.

OccuType **Section content:** Occupation related info.

OccuType%chbnds

> **Type** bool
>
> **Description** Technical option about skipping bands.

OccuType%dfermi

> **Type** float
>

PeriodicZlmFit **Section content:** ZlmFit info related to periodic systems.

PeriodicZlmFit%aVec

Type float_array

Description The lattice stored as a 3xnLatticeVectors matrix. Only the ndimk,ndimk part has meaning.

Unit bohr

Shape [kspace%ndim, kspace%ndim]

PeriodicZlmFit%cellCenter

Type float_array

Description Origin of the cell.

Shape [3]

PeriodicZlmFit%cellMultipoles

Type float_array

Description Multipole coefficients for the cells. Dimension: self%zlmFit%lMax+1)**2

Shape [:]

PeriodicZlmFit%fGaussianW

Type float

Description Width for the gaussians around atom centers. (Only 3D)

PeriodicZlmFit%fGridSpacing

Type float

Description Spacing for the fourier grid. Only used for 3D periodic systems.

PeriodicZlmFit%firstTopoCell

Type int

Description First cell from whereon the fitting of the topological extrapolation is started.

PeriodicZlmFit%fKSpaceCutoff

Type float

Description Cutoff criterion used in k-space. (Only 3D)

PeriodicZlmFit%fMultipoleCoeff

Type float_array

Description Atomic multipole cofs.

> **Shape** [nAtoms, nMultipolesFourier]

PeriodicZlmFit%lastTopoCell

> **Type** int

> **Description** Last cell from whereon the fitting of topological extrapolation is started. For cells>lastTopoCell the extrapolation is used.

Description Whether or not to prune.

PeriodicZlmFit-ZlmFit%pruningL

Type int

Description ?.

PeriodicZlmFit-ZlmFit%pruningThreshDist

Type float

Description Distance threshold for pruning.

Unit bohr

PeriodicZlmFit-ZlmFit%radialGrid

Type float_array

Description Radial grids per atom.

Shape [nAtoms, maxNPointsRadGrid]

PeriodicZlmFit-ZlmFit%sizeProjCoeff

Type int

Description ?.

PeriodicZlmFit-ZlmFit%xyzAtoms

Type float_array

Description Atom coordinates.

Unit bohr

Shape [3, nAtoms]

phonon_curves **Section content:** Phonon dispersion curves.

phonon_curves%brav_type

> **Description** Characterization of the critical points. 1: (3,-3) atom critical point. 2: (3,+3) cage critical point. 3: (3,-1) bond critical point. 4: (3,+1) ring critical point.
>
> **Shape** [CP number of]

Properties%CP coordinates

Type float_array

Description Coordinates of the critical points (QTAIM).

Shape [3, CP number of]

Properties%CP density at

Type float_array

Description Density at the critical points (QTAIM).

Shape [CP number of]

Properties%CP density gradient at

Type float_array

Description Gradient of the density at the critical points (QTAIM).

Shape [3, CP number of]

Properties%CP density Hessian at

Type float_array

Description Hessian of the density at the critical points (QTAIM). Compressed symmetric storage.

Shape [6, CP number of]

Properties%CP number of

Type int

Description Number of critical points for the density (QTAIM).

Properties%nEntries

Type int

Description Number of properties.

Properties%Subtype(#)

Type string_fixed_length

Description Extra detail about the property. For a charge propety this could be Mulliken.

Properties%Type(#)

Type string

Description Type of the property, like energy, gradients, charges, etc.

Properties%Value(#)

Type float_array

Description The value(s) of the propety.

radial Section content: A system can be built up from fragments, allowing an energy decomposition. The bonding energy will be with respect to the fragments.

radial%cutoff

Type float

Description Cutt off criterion for the radial tables.

radial%ncelforscreening

Type int

Description Number of cells needed for screening (obsolete).

radial%ncore

Type int_array

Description Number of radial core functions per type.

Shape [geometry%ntyp]

radial%nfit

Type int_array

Description Number of radial core functions per type.

Shape [geometry%ntyp]

radial%nr

Type int_array

Description Number of radial points per type.

Shape [geometry%ntyp]

radial%nrx

Type int

Description Maximum number of radial points for any type.

radial%rad

Type float_array

Description Maximum number of radial points for any type.

Shape [nrx, geometry%ntyp]

radial%xyzcelforscreening

Type float_array

Description Cell coordinates needed for screening (obsolete).

Shape [3, ncelforscreening]

radial tables type# **Section content:** Information about the eigensystem.

radial tables type#%alj

Type string

Description Labels for the valence orbitals with each label having a length of six characters.

radial tables type#%d2rho

Type float_array

Description Second derivative of the density.

Shape [nRadialPoints]

radial tables type#%dfxc

Type float_array

Description Derivative of the XC energy density.

Shape [nRadialPoints]

radial tables type#%drho

>   **Type** float_array

SystType%ncores

> **Type** int
>
> **Description** Number of frozen core functions.

SystType%ncorex

> **Type** int
>
> **Description** Obsolete, not used. Maximum nr. of radial core functions per type.

SystType%ncorez

Type int

Description Number of slater type core functions (obsolete, not used).

SystType%nfitt

Type int

Description Number of STO fit functions.

SystType%nfitx

Type int

Description Maximum number of radial STO fit functions per type.

SystType%nfrag

Type int

Description Number of fragments to be used for the calculation.

SystType%ngross

Type int

Description Number of user requested gross populations to print.

SystType%noverl

Type int

Description Number of user requested overlap populations to print.

SystType%nspin

Type int

Description Number of spin components for the eigenvectors. 1) Spin restricted, 2) Spin unrestricted: eigenvectors can be symmetry labeled up or down.

Possible values [1, 2]

SystType%nspino

Type int

Description Number of spin components for the basis set. 1) Scalar or non relativistic, 2) Spin orbit. With nspino=2 nspin=1, as eigenvectors do not have a up or down symmetry label. The density has max(nspin,nspin) components. In case of noncollinear magnetization it even is a 2x2 complex Hermitian matrix.

Possible values [1, 2]

SystType%nsymft

Type int

Description Number of symmetric STO fit function combinations.

SystType%nvalx

Type int

Description Maximum number of radial valence functions per type.

SystType%qelec

Type float

Description The number of valence electrons (not including a nett charge of the system).

SystType%Serializer::type

       Type string_fixed_length

       Description Information for the Serializer code.

SystType%vsplit

       Type float

       Description Add vsplit to the spin up potential at the first SCF cycle to break the initial exact spin symmetry.

SystType%xcpar

       Type float

       Description x-alpha parameter.

SystType%zora

       Type bool

       Description Whether to use the relativistic ZORA approximation (zora=yes) or the nonrelativistic one (zora=no).

FAQ

14.1 Where can I find the total energy in the BAND output?

BAND does not calculate the total energy. Instead, it calculates the formation energy with respect to the spherically symmetric spin-restricted atoms. The reason is that this number is easier to determine accurately using numerical integration then the total energy.

14.2 What to do with this PEDA ERROR? ERROR DETECTED: Fragments cannot be assigned by a simple translation!

The problem is that BAND is (internally) centralizing the atom positions with respect to the geometrical center of the structure. During this centralization an atom can be positioned on one side of the unit cell or the other. (the result for this individual calculation will be the same in both cases, but for a PEDA calculation that is not true) In your case, the centralization of the fragments and of the PEDA calculation gave results which cannot be transformed into one another by a simple translation.

The solution is to pre-centralize the whole system with respect to the geometrical center of the "bigger" fragment. (since this fragment usually gives this problem) E.g. if you study a surface-adsorbate interaction, you centralize the whole structure w.r.t. the geometrical center of the surface. In some cases the adsorbate fragment might be the reason of the problem. If so, we recommend redefining the unit cell so that the adsorbate is closer to the center of the unit cell than to any of the borders of the unit cell.

If this approach does not solve your problem please send us (support@scm.com) your input and output, so we can look into it.

14.3 What are the units in the Density Of States (DOS) plot?

The dimension of the "density of states per unit cell" (DOS)

$$D(E) = \int_k dk \sum_n \delta(E - \epsilon_n(k))$$

is [1/(energy)].

As the number of states at precisely one energy can be a very wild function an average is plotted (not affecting the unit)

$$D^{\text{smoothed}}(E) = \frac{1}{\Delta_E} \int_E^{E+\Delta_E} D(e)\, de$$

The bin-width Δ_E is controlled by the input option DOS%DeltaE. To obtain the exact non-smoothed dos, set the Dos%IntegrateDeltaE option to "false". As stated before: the non-smoothed DOS will be a very wild function, and for instance bands with little dispersion may be completely missed.

14.4 Why do I get negative partial Density Of States (partial DOS)?

The negative values in the partial DOS are artifacts due to the fact that in a non-orthogonal basis set the definition of a "partial DOS" is somewhat arbitrary. The partial DOS can be a useful tool for understanding the physics/chemistry of your system, but it's strictly speaking not a "physical quantity".

14.5 Why is the DOS zero in an interval with bands?

Quite often there is missing DOS: in an energy interval where there are clearly bands there is no DOS. This is an artifact of using insufficient k-sampling. The simple solution is to redo the whole calculation with a finer k-grid. However, it turns out that the finer grid is only really needed for the DOS, and *restarting the DOS* (page 162) with a finer k-grid is usually sufficient to solve such a problem.

14.6 Is the absolute value of the Fermi energy physically meaningful?

Absolute values of orbital energies are physically meaningful for non-periodic systems, 1D periodic systems and 2D periodic systems. For these cases, E=0 corresponds to the energy of a free electron and the absolute value of the Fermi energy is equal (to a first approximation) to the work function.

In 3D periodic systems the orbital energies (and Fermi energy) are defined up to a constant, ergo the absolute value of energy bands does not have a clear physical meaning (we nonetheless use the convention of setting V_{k=0} = 0, like most other programs).

14.7 Why does the band structure of Graphene look wrong?

There can be some issues. The first problem can be that a super cell is used. The smallest possible (primitive) cell has only two atoms in the unit cell. Only when using the primitive cell, the crossing of two bands at the fermi energy in the point with symmetry label "K" can be seen.

Even when using the primitive cell, the fermi energy may be off: it is not exactly where the two bands cross at "K". This can happen when the grid used during the SCF (or during the SCC of DFTB) does not contain the point "K". The simplest way to solve this is to switch to the symmetric grid and use for instance kInteg=5.

```
KSpace
    Type Symmetric
    Symmetric
        KInteg 5    # Should be an odd number bigger than 1. This value is good for␣
↪Graphene
    End
end
```

You can also achieve this via amsinput. Go to Details -> K-Space integration. Set K-space grid type to "Symmetric" and enter 5 in "Accuracy".
